APPENDIX - Gravity Survey -  
Tabulated Station Values

### 1. SUMMARY

Interpretation of modelling of magnetic Anomaly B detected in the 1978 airborne survey indicated a weak source at 500-600 m or 930 m depth, depending on the model used. A ground magnetics and gravity survey was undertaken to aid modelling. The continuity of Anomaly A was modelled but drilling has only intersected a barren magnetite-bearing metasedimentary unit. Further drilling of magnetic anomalies has not been recommended.

### 2. INTRODUCTION

EL 1951 Alroy North of 31.1 sq miles was applied for on 26th September, 1978 by CRA Exploration Pty Ltd (see Plans NTd 1006 and 1180). The area was granted by the N.T. Government on 23rd January, 1979 and on 26th March, 1979 was included in the joint venture agreement with Australian Ores and Minerals Ltd (A.O.M.), which was initially signed on 28th August, 1978. The exploration strategy was to prospect for concealed Tennant Creek style mineralisation in what were assumed would be Lower Proterozoic rocks beneath the Palaeozoic sediments of the Georgina Basin. Exploration activities during the first year of tenure to 22nd January, 1980 are described by Steemson (1980). This report covers the period from that date until relinquishment of the exploration licence.

### 3. CONCLUSIONS

Neither further drilling of Anomaly A, into which 2 holes have already been drilled, nor drilling of the deeper Anomaly B is warranted. Both drill holes intersected a barren Middle Proterozoic magnetite-bearing metasedimentary unit which probably continues at depth to Anomaly B where the anomaly is produced by an anticline similar to that at Anomaly A.

#### 4. GEOLOGY

As can be seen in Plan NTd 993 the Alroy North EL 1951 area is completely covered by Cainozoic fine red sand, most of which was once wind-borne, but now forms broad, low, vegetated dunes which are elongated many miles in the NW-SE direction of the prevailing south-easterly winds. There are minor patches of black soil, gravel, travertine, detrital laterite and red clayey soil. Beyond the EL area to the south-west and south-east are low outcrops of fossiliferous Middle Cambrian silicified limestones and dolomites, with interbedded siltstones and chert silicified shales. These are the Wonorah Beds of the Georgina Basin sequence and underlie the Cainozoic sand cover in the EL area.

#### 5. PREVIOUS WORK

An airborne magnetometer and differential spectrometer survey was flown over the area late in 1978, the specifications of which were reported by Steemson (1980). No significant radiometric anomalies were detected by that survey. Evaluation of residual total field magnetic contours and stacked profiles indicated two anomalies, designated Anomaly A and Anomaly B (see Plans NTd 1430 and 1015), were comparable to magnetic features associated with Tennant Creek style copper-gold mineralisation.

Anomaly A was investigated, gridded and ground magnetics read over it by contractors (see Plan NTd 1431). From the ground magnetic profiles modelling was done in order to plan drill testing of the anomaly. DD79ALL was finally collared at 9796N 10 000E but was abandoned at 193.1 m due to caving, the target not having been intersected. Plan NTd 1181 shows the drill section.

#### 6. GEOPHYSICAL MODELLING

Magnetic modelling of Anomaly B was undertaken prior to ground investigation. Two lines, T94 and T95, from the airborne data were digitised and models constructed

to compare with these profiles (Bronskill, 1980). The models in Figures 1 and 2 resulted. A magnetic body at 500-600 m depth, about 450 m thick and with a susceptibility of .002 - .003 cgs matches the observed anomaly reasonably well.

Another model, the PRISM model, representing a dipping prism of finite strike, length and depth extent with sides orthogonal to its strike being vertical, was also run on the computer with data obtained by digitizing the aeromagnetic contour map on 800 m x 400 m centres (Jenke, 1980). The results are shown in Figures 3 and 4, the latter being a copy of the computer printout, and indicate a magnetic body about 1000 m below the sensor height (nominally 90 m) and dipping steeply to the north at 74°.

Detailed magnetic modelling of Anomaly A is discussed by Snelling (1980 a,b) and Steemson (1980). However, the continuity of the magnetic body at Anomaly A was tested by modelling from ground profiles its western extent in EL 1951 (Jenke, 1980). Lines 8400E and 8800E were chosen. The TABULAR model, representing a two dimensional dyke of infinite depth extent was used. The results are as follows:-

	k (c.g.s.)	Dip (°S)	Range on line	Depth (m)	True Width (m)
8400E	0.00248	65	9835N- 10022N	220	169
8800E	0.00190	67	9794N- 10104N	183	285

The parameters from the MAGMOD programme were used to calculate the response of such a body, and the results plotted in Figures 5 and 6 agree well with the observations. The susceptibilities, which were established by trial and error, are within a few percent of those which can be calculated from the MAGMOD results. When compared with the previously established modelling results (Snelling, 1980a and Steemson, 1980) as shown in Figure 7, there is an indication that the depth to this body increases from the centre towards each end. However, this is more likely to be a result of the body's limited strike length when the model used for interpretation assumes an

infinite strike extent, and the estimates from the centre of the response are likely to be the most accurate.

The dramatic change in the interpreted depth below ground level from "A" body (150 m) to "B" body (930 m) suggests that the source of each response may be a common geological unit downfaulted in the position of "B" body. A simple model of that situation (Figure 8) was run on the computer and showed that such a possibility could easily be checked with a gravity survey.

#### 7. GROUND MAGNETICS - ANOMALY B

Anomaly B was located in the field by extending the baseline from Anomaly A to the appropriate grid coordinates derived from the aeromagnetic data. A 4 km N-S traverse was made along line 4800E with a Scintrex MP-2 magnetometer. The resultant magnetic profile is plotted on Plan NTd 1435 and closely matches those in Figures 1 and 2.

#### 8. GRAVITY SURVEY

Gravity readings were taken at 50 m intervals along optically levelled lines 10 000mE, 10 400mE and 10 800mE from 9000mN to 11 000mN, and along 10 000mN from 10 000mE to 10 800mE (Plan NTd 1495). Barometric levelling was used for stations at 400 m intervals along the baseline from 2800mE to 10 000mE, and at 500 m intervals along the access track into the prospect (Plans NTd 1438 and 1439). For the latter traverse, the station positions are estimated only.

The following factors were used for the reduction of the data:-

Grid North:	347° True
Latitude Correction:	0.000517 mgals/m N-S
Bouguer Density:	2.3t $m^{-3}$
Elevation Correction:	0.212312 mgals/m
Base Station Location:	10 600mE 10 000mN
Base Station Value:	2080.00 mgals

The meter used was a Lacoste and Romberg (serial no.544), and in general readings repeated to within  $\pm 0.02$  mgals.

Individual station values are tabulated in the Appendix.

Barometric levelling was used to tie the RL's established on the prospect to bench marks located on the Barkly Highway. Using the elevations shown on the published 1:500 000 Bouguer Anomaly map, the grid RL of 100.00 m corresponds to an elevation of 239.0 m (784 ft).

Average difference in gravity readings between the bench marks and the prospect base station at 10 600mE 10 000mN are as follows:-

Bench Mark	Gravity (mgals) relative to 10 600mE 10 000mN
8917	-24.67
8918	-21.58
8919	-11.61
8920	-12.76

Because the location of the grid is not accurately known, no attempt has been made to relate the prospect data to the BMR measurements at these base stations.

No detailed interpretation of this data has yet been attempted.

#### 9. DISCUSSION

The depth of 500 m - 600 m or 930 m, depending on which magnetic body model is accepted, and the low susceptibility (.002-.003 or .0075 cgs, lower than the .04 cgs measured on drill core from hole DD79AL2 over Anomaly A, EL 2043 Dalmore - see Snelling, 1980b) do not make Anomaly B an attractive target. Furthermore, since it is postulated that Anomalies A and B may actually be connected and therefore represent the same magnetic source, the drilling results from Anomaly A (Snelling, 1980a,b) are significant. The two holes drilled both intersected a barren magnetite-bearing metasedimentary unit, interbedded with dolomites that contain stromatolites of Middle Proterozoic age, not a Tennant Creek-type ironstone lode in Lower Proterozoic clastics. Thus it is considered that further drilling of Anomaly A is not warranted; neither is drilling of the

deeper Anomaly B, where the anomaly is probably produced by an anticline similar to that at Anomaly A.

FLOWN FOR CRA EXPLORATION BY GEOMETRICS  
GEOMETRICS JOB NUMBER 9187  
DECEMBER, 1978

SURVEY SPECIFICATIONS

MAGNETOMETER: GEOMETRICS G-803 PROTON PREcession  
SENSITIVITY: 0.5 NANOTESLAS  
FLIGHT LINE DIRECTION: NORTH TO SOUTH  
FLIGHT LINE SEPARATION: 500 METRES  
MEAN TERRAIN CLEARANCE: 90 METRES  
ALONG LINE SAMPLING: 50 METRES

SURVEY FLOWN BY DOPPLER  
IGRF REMOVED

CONTOUR INTERVAL 5 NANOTESLAS

SCALE 1:100,000
