Report number

15229

CONTENTS

1 SUMMARY

In the first year of tenure of Snake Creek EL 1990, a detailed airborne magnetic and radiometric survey was flown over the EL area.
No uranium-channel anomalies were observed in the survey data; seven magnetic anomalies were selected for investigation as possible kimberlitic diatreme responses.

In tenure year two, reconnaissance drainage gravel sampling, for detection of kimberlitic indicator minerals, was undertaken in those parts of the EL area with a developed drainage system.
Single microdiamonds were reported in four samples.
A picroilmenite grain and a microdiamond were detected in one sample from upper Snake Creek.

An airborne "DAEDALUS" multispectral scanner survey was flown over the EL area in September 1984.

In a reduced tenement area in tenure year three, follow-up drainage sampling resulted in detection of:
one chromite grain and a microdiamond in a check resample of the site, on a Calvert River headwaters tributary, of a previously reported microdiamond;
two microdiamonds in an upstream follow-up sample from this tributary;
one microdiamond in an infill sample from a Calvert River headwaters tributary; and
three chromite grains and two microdiamonds in a check sample from upper Snake Creek.

Five aeromagnetic anomalies were ground recovered for investigation as possible diatreme responses.
Ground survey profiles over anomalies SNC 1, SNC 2 and SNC 5 showed complex dipolar responses, with interpreted shallow magnetic sources concealed by soil cover.
The source of anomalies SNC 3 and SNC 4 was interpreted to be aliasing effects over concentrations of magnetic pisolites.

In loam samples taken over response centres, single microdiamonds were reported in each of two samples from SNC 1 and one from SNC 2. Two microdiamonds were reported in a loam from SNC 5.

15 airphoto features, with anomalous DAEDALUS spectral signatures, were ground recovered for investigation as possible diatreme suboutcrop expressions.
Features were found to correspond most commonly with localised areas of pisolitic/ferruginous and/or clay-rich soils, typically developed on lateritised Cretaceous sediments or in drainage swales or soaks.
Five features were loam sampled with negative result.

Anomalous responses were observed in ground magnetic survey data from features 4/3/14 and 5/4/19.
Ground magnetic profiles showed no discrete responses corresponding with five other surveyed features.

In a further reduced tenement area in tenure year four, three drainage samples were collected from minor tributaries of upper Snake Creek and four loam samples were collected from subtle photofeatures in the Snake Creek headwaters area.
One microdiamond was reported in one of the drainage samples; results were otherwise negative.

Additional ground magnetic data, infilling field season 1986 surveys, were acquired on four DAEDALUS/airphoto features.
A magnetic dipole, with interpreted source depth ~50m, was confirmed to coincide with feature 4/3/14.
Discrete magnetic source bodies were not confirmed to correspond with features 2/4/7, 3/2/8 or 5/4/19.

A program of bedrock auger sampling was undertaken to investigate suboutcrop geology of aeromagnetic anomalies SNC 1, SNC 2 and SNC 5 and DAEDALUS/airphoto features 2/4/7, 3/2/8, 4/3/14 and 5/4/20.
SNC 1, SNC 2 and features 2/4/7, 3/2/8, 4/3/14 and 5/4/20 were shown to be underlain by lateritized sandstones.
SNC 5 auger cuttings logs showed weathered "doleritic" volcanics beneath 10-15m of red sand.

Two microdiamonds were reported in one cuttings sample and single microdiamonds in two others from SNC 1; single microdiamonds were reported also in one cuttings sample from each of SNC 2 and 2/4/7.
Analyses of bottom-hole cuttings samples did not show any geochemical signature suggestive of kimberlitic lithology.

2 ASSESSMENT

Drainage gravel, loam and bedrock auger sampling programs have confirmed significantly anomalous concentrations of kimberlitic indicator minerals (notably microdiamonds) in the Snake Creek drainage catchment area. No primary source kimberlitic diatreme has been identified or vectored by locally detailed follow-up investigations.

From review of results overall, it is considered probable that microdiamonds are being shed locally from a secondary detrital source. In the light of this interpretation, it is considered that the prospect of locating a diamondiferous diatreme in the reduced EL 1991 area has been downgraded to the extent that no further exploration can be recommended.

3 INTRODUCTION

Snake Creek EL Application 1991 was lodged on 17 November 1978, for an area of 380 blocks (about 1224 square km; location shown on plan NTd 4552) and was granted on 7 July 1983.
Tenement was taken up for exploration primarily for Westmoreland-style uranium mineralization, hosted in Lower Proterozoic Tawallah Group Westmoreland Conglomerate and Seisal Volcanics.

The EL 1991 area is on an easterly-projecting 'headland' of the Barkly Tableland plateau surface, developed on lateritized Mesozoic sedimentary rocks, flanked by drainage basins of the Calvert River system to the north and the Nicholson River to the south.

Pre-Mesozoic bedrock geology of most of the EL area is concealed by lateritic residual soils and drift sand. Some outcrops of Westmoreland conglomerate are mapped in central and southern sectors (Yates et al, 1963); published regional aeromagnetic data (BMR, 1978) was interpreted to suggest continuation of a belt of the 'Peters Creek Volcanics' (= Seisal Volcanics of Mitchell et al, 1980) at shallow depth through the EL 1991 area.

Statutory reduction of tenement area at the end of tenure year two resulted in retention of an area of 189 blocks (about 617 square km) into tenure year three.
Statutory reduction of tenement area at the end of tenure year three resulted in retention of an area of 94 blocks (about 307 square km) into tenure year four.
Statutory reduction of tenement area at the end of tenure year four resulted in retention of an area of 47 blocks (about 153 square km) into tenure year five (plan NTd 4552).

Surrender of EL 1991 was accepted with effect on 11 June 1988

4 AIRBORNE GEOPHYSICAL SURVEY

A detailed low-level airborne magnetic and radiometric survey was flown over the EL 1991 area by Geoterrex Pty. Ltd. in May-June 1984.

4.1 Control Photography

Navigation and flight path recovery of the airborne geophysical survey were carried out on 1:25 000 black-and-white enlargements of 1:80 000 colour photography flown in May 1983 by Aerial Surveys Australia Pty.Ltd.
To establish control, nine photogrammatic control points were plotted on alternate frames by Peter Livings and Associates, Perth, using data supplied by the Department of National Mapping, Canberra.

4.2 Survey Parameters

In summary, parameters of the airborne geophysical survey were:

Contractor	: Geoterrex Pty.Ltd. (acquisition and processing)
Survey name	: Snake Creek
Survey area	: 1224 square kilometres
Flight line direction	: North-south
Flight line spacing	: 300 metres
Tie line direction	: East-west
Tie line spacing	: 4 kilometres
Nominal terrain clearance	: 80 metres
Nominal flying speed	: 65 metres/second
Magnetometer	: Varian cesium vapour (0.04nT)
Cycling interval	: 0.2 seconds
Spectrometer	: Nuclear Data ADC/ND-560
Crystal volume	: 33.5 litres
Cycling interval	: 1 second

The Geoterrex logistics report was reproduced in full as an appendix to CRAE report 130522 (Bubner, 1985).

4.3 Survey Data Processing

Geoterrex data processing included the production of flight path plans and stacked magnetic profiles plans at 1:25 000 scale (plans NTd 3469-3490, accompanying CRAE report 130522: Bubner, 1985).

From located data tapes delivered by Geoterrex, the CRAE Research Group in Canberra undertook COMTAL system computer processing to produce images of raw and derivative-enhanced magnetic and radiometric data.
Selected data images were copied to 35mm slide sets for review and interpretation.

4.4 Review Of Radiometric Data

Data were reviewed as analogue records and COMTAL images.
Some relief was noted in K- and Th-channel responses, commonly relating to drainage and outcrop/subcrop patterns.
No elevated U-channel responses were detected, either as spot highs on analogue records or as subtle features on COMTAL images.

4.5 Interpretation Of Magnetic Data

The new magnetic data were observed to support in detail the interpretation from published regional aeromagnetic data (BMR, 1978) of continuation of a belt of Seigal Volcanics at shallow depth through the EL area. An aeromagnetic interpretation of the subsurface geology of the EL area is shown in plan NTd 4019.

Stacked profiles and COMTAL images were reviewed for selection of discrete magnetic features, for investigation as possible kimberlitic diatreme responses. High magnetic relief precludes recognition of such features over much of the survey area: seven anomalies were identified in areas of relatively subdued magnetic background.
Anomalies are tabulated in Appendix 1;
locations are shown on plans NTd 3874 and 4019.

Aeromagnetic anomaly investigations are discussed in section 7 of this report.

5 DRAINAGE GRAVEL SAMPLING

Sampling programs were helicopter supported, with -2mm sieved drainage gravel samples collected from heavy mineral accumulation (trap) sites where available.

In the absence of well developed drainage, 'loam' samples of about 50-100kg of surficial soil, shallowly scraped over an area of several square metres to take advantage of any concentration of heavy mineral grains by soil deflation, were collected from sheet wash drainage swales, magnetic anomaly centres and photofeatures.

Samples were forwarded to the CRAE Belmont laboratory for processing for kimberlitic indicator mineral observation and detection of microdiamonds (<0.4mm).
Sample locations are shown on plan NTd 4020.
Sampling data and results are tabulated in Appendix 3 and discussed below.

5.1 Reconnaissance Sampling

Some 30 samples (1081-series numbers) were collected in reconnaissance drainage gravel sampling of the EL area; in a very uneven coverage, due to absence of a developed drainage system over large parts of the area.

One picroilmenite grain and one microdiamond were reported in sample 1081126, from the upper course of Snake Creek.
Single microdiamonds were reported in each of samples 1081125, from a Snake Creek tributary, downstream from the sample 1081126 site; and
1081470, 1081473 & 1081475, from Calvert River headwaters tributaries in the northeastern sector of the EL area.

5.2 Field Season 1985 Check Sampling

Two x100kg check samples (1084822 & 1084823) were collected at the recovered sites, on Calvert River headwaters tributaries, of reconnaissance drainage gravel samples 1081481 (negative) and 1081473 (one microdiamond reported).

Sample 1084822 gave negative results.
One chromite grain and one microdiamond were reported in sample 1084823.

5.3 Field Season 1986 Follow-up Sampling

A program of drainage sampling was undertaken in field season 1986, to follow up positive results reported from reconnaissance and check sampling and to infill sampling coverage of areas of developed drainage.
30 -2mm sieved drainage gravel samples (numbered in the series 1312088-1312138) were collected, including resamples bulking ~100kg, taken at recovered sites of reconnaissance samples with positive results.

One microdiamond was reported in infill sample 1312091, from a Calvert River headwaters tributary;
two microdiamonds were reported in follow-up sample 1312098, from a Calvert River headwaters tributary ~1km upstream from the site of samples 1081473 (one microdiamond) and 1084823 (one chromite and one microdiamond); and
three chromite grains and two microdiamonds were reported in check drainage sample 1312116, from upper Snake Creek ~400m downstream from the site of sample 1081126 (one picro-ilmenite and one microdiamond).

5.4 Field Season 1987 Follow-up Sampling

In field season 1987, drainage gravel samples 1312036-038 were collected from minor tributaries of Snake Creek, close upstream from sample site 1081126.

One microdiamond was detected in sample 1312036: reports were otherwise negative.

6 AIRBORNE MULTISPECTRAL SCANNER SURVEY

In September 1984, an airborne multispectral scanner survey was flown over the EL area with a 'DAEDALUS' DS-1268 system operated by the National Safety Council of Australia (Victorian Branch).

A flight line diagram is shown on plan NTd 4013.

In summary, the survey parameters were:

Aircraft	:	Beech King Air
Survey altitude	:	8000 metres
Ground speed	:	240 knots (approx.)
Flight line direction	:	north-south
Pixel size	:	20 metres
Swath	:	13.5 km (approx.)
Overscan	:	x 2
Overlap	:	40%
Channels	:	0.42 - 0.45um (ch.1)
		0.45 - 0.52 2
		0.52 - 0.605 3
		0.605 - 0.625 4
		0.63 - 0.69 5
		0.695 - 0.75 6
		0.76 - 0.9 7
		0.91 - 1.05 8
		1.55 - 1.75 9
		2.08 - 2.35 10
		8.5 - 15um 11

Data processing was undertaken by the CRAE Research Group in Canberra.
Data images, generated by assigning primary color components to selected spectral data channels or channel ratios were hard-copied to 35mm slides.

For the 'Snake Creek area' survey data, two sets of slide images were produced with the following selections:

Set 1:	red	= channel 7
	green	= channel 5
	blue	= channel 3
Set 2:	red	= channel 9 / channel 10
	green	= (-)channel 11
	blue	= channel 9 / channel 7

From these slide sets, numerous areas of anomalous response were identified; commonly observed to correspond with topographic / soil tone features identifiable on aerial photographs.
A tabulation of DAEDALUS features is included in Appendix 2; locations are shown on plan NTd 3874.
Ground investigations are discussed in section 7 of this report.

7 AEROMAGNETIC & DAEDALUS/PHOTO-ANOMALY INVESTIGATIONS

In field seasons 1985-86, five aeromagnetic anomalies and 15 DAEDALUS/photo-anomalies, within the third tenure year EL 1991 boundaries, were ground recovered for investigation as possible diatreme expressions. These investigations (reported by Colliver & Bubner, 1986) included ground magnetic surveys, outcrop and loam sampling.

Follow-up investigations in field season 1987 (Colliver & Bubner, 1987) included also a program of bedrock auger sampling.

7.1 Ground Magnetic Surveys & Surface Sampling

Ground recovery of aeromagnetic anomalies and DAEDALUS/photofeatures was helicopter supported, using for navigation 1:25 000 black and white airphoto enlargements marked with estimated anomaly centres.

For each ground magnetic survey, a permatagged steel star picket, assigned local grid origin co-ordinates 1000mE 1000mN, was placed at or near the recovered anomaly centre. Temporary survey lines were established by topofil and compass on magnetic N-S/E-W bearings and marked by flagging tape at 50 metre intervals.

Readings of the total magnetic field were acquired at 10m intervals using Scintrex MP3 magnetometers, with the sensor on a two metre staff.
Magnetic data were corrected for diurnal variation, monitored by a base station MP3 located at Calvert River base camp (field seasons 1985-1986) or Horse Creek base camp (field season 1987). Data were stored on cassette using a HP-85B microcomputer and transcribed subsequently to a Microvax at CRAE Adelaide office.

In field seasons 1985-1986, 42.6 line-km of ground magnetics data were acquired over aeromagnetic anomalies SNC 1-SNC 5 and 9.2 line-km over Daedalus/photofeatures 2/4/7, 4/3/14, 4/4/15, 4/4/16, 4/5/17, 5/4/19 and 5/4/20.
Additional ground magnetics data were acquired in field season 1987 over features 2/4/7, 3/2/8, 4/3/14 and 5/4/19, for final screening of target selection for a planned program of Gemcodrill auger sampling.
Ground magnetic survey profiles are shown on plans NTd 4173 -4177, NTd 4472 and NTd 4560-4566.

Over shallow anomaly centres, 'loam' samples of about 100kg of surface soil were shallowly scraped to take advantage of any winnowing concentration of resistate heavy mineral grains. Loam samples were processed by the CRAE Belmont laboratory for detection of kimberlitic indicator minerals and microdiamonds.
Sample locations are shown on plan NTd 4020;
results are tabulated in Appendix 3.

Anomaly SNC 1

This anomaly is defined on the airborne stacked profiles as a dipolar feature of up to 18nT amplitude over three flight lines, and appears to represent a component of the total magnetic response of a source extending to the north-east. The anomaly is located in a magnetically 'quiet' area, and the amplitude is much less than typically associated with volcanic-sourced anomalies.

11.1 line-km of ground traverses were completed to define the anomaly and associated responses to the north-east.
The airborne responses are confirmed by dipoles on lines 800mE to 1300mE between 600mN and 900mN, 'reversed' dipoles on lines 1000mE and 1100mE at about 1400mN, and highs on lines 1200mE and 1300mE between 1500mN and 2000mN (plan NTd 4173).
Data to the south of 1000mN and east of 1200mE are generally smooth; elsewhere single-reading noise spikes of amplitude typically 100nT are superimposed on the magnetic anomalies.

The geometry of the dipoles and 'reverse' dipoles suggests responses of the southern and northern edges respectively of a relatively shallowly concealed flat-lying sheet. In the absence of any control it is difficult to quantify the source of the magnetic high between 1500mN and 2000mN, although analysis of the airborne data in a regional context suggests it to be the western end of a deep, broad magnetic feature plunging shallowly to the east.

No outcrop was observed within the grid area. Cover is of khaki sandy soil, with variably abundant pisolites and scattered pebbles and cobbles of laterite and ferruginous sandstone.
Loam sample 1084824 was taken in field season 1985 at 900mE 1200mN. One microdiamond was reported.
Check loam sample 1312138 was taken in field season 1986 at 1200mE 800-850mN. One microdiamond was reported.

Anomaly SNC 2

This anomaly comprises well-defined dipoles of amplitudes 110nT and 165nT on two flight lines. In a regional context, the anomaly occurs within a magnetically disturbed zone, interpreted to represent a belt of volcanics (plan NTd 4019).

Ground investigations included 6.2 line-km of magnetometer traverses.
All profiles display well-defined dipoles of up to 360nT amplitude and wavelength of 300-400m (plan NTd 4174). Irregularities within the profiles suggest a complex source or multiple sources: that is, although profiled responses are broadly dipolar, the shapes of peaks and troughs are inconsistent with a discrete, "infinite" depth-extent source. The anomaly was rather interpreted to represent responses to the northern and southern edges of a relatively shallowly concealed flat-lying source body.

The recovered aeromagnetic anomaly coincides with a local low rise of grey hard sandy soil cover, with patches of non-magnetic laterite, pisolite accumulations and some ferruginous (Cretaceous?) sandstone scree.
Loam sample 1084825 was taken in field season 1985 at 1000mE 780mN. One microdiamond was reported.

Anomaly SNC 3

Five line-km of ground magnetics data were acquired to investigate a 4nT dipolar anomaly on one flight line.
Profiles on all traverses display single-reading noise spikes with amplitudes typically in excess of 100 nT (plan NTd 4175).

No outcrop was observed in the grid area. Ferruginous-cemented sandy detritus and sandstone scree are scattered about and pisolites are abundant in the sandy soil. Magnetic susceptibility readings on the pisolites gave values of 0.01-0.02 SI units.
The source of the airborne anomaly is interpreted to be aliasing effects over the magnetic pisolites.
Loam sample 1084827 was taken in field season 1985 at 1000mE 1000mN. No indicator minerals or microdiamonds were detected.

Anomaly SNC 4

This anomaly is a 4nT dipole on one flight line in a magnetically quiet area. 4.2 line-km of ground magnetics data were acquired on one east-west and four north-south traverses.
The profiles on all traverses are dominated by single-reading noise spikes, with amplitudes typically in excess of 100 nT (plan NTd 4176).

Grey sandy soil covers the grid area, with some ferruginous-cemented sandstone detritus and magnetic pisolites.
The source of the aeromagnetic anomaly is ascribed to aliasing effects over the pisolites.

Anomaly SNC 5

This anomaly is a 5nT inflexion on one (possibly continuing through to a second) flight line. It is located on the southern margin of a zone of complex magnetic relief, interpreted to be caused by a suboutcrop belt of Tawallah Group Seisal Volcanics (plan NTd 4019).

16.1 line-km of ground magnetometer traverses were completed on three east-west and nine north-south lines. The profiles are mostly devoid of noise spikes, and display several distorted dipoles up to 100 nT in amplitude (plan NTd 4177). The airborne response is confimed by a multiple-source(?) dipole extending from 800mE to 1600mE, between 1100mN and 1300mN. The irregular magnetic relief in the profiles is suggestive of a volcanic sheet source: however, in a regional context, the feature is discrete - located outside the boundary of an interpreted belt of Seisal Volcanics.

The central part of the grid area corresponds with a belt of eucalypt forest on red-brown sandy-silty soil, flanked to the north by beige silty sand with casuarina scrub and to the south by a sandstone subcrop area with light scrub and grass cover.
Loam sample 1084834 was taken in field season 1985 at 1300mE 1150mN. Two microdiamonds were reported.
Loam samples 1312136, 1312137 were taken in field season 1986, respectively at 1100mE 1150mN and 1100mE 1450-1500mN. No kimberlitic indicator minerals or microdiamonds were detected.

DAEDALUS feature 2/3/5

The DAEDALUS anomaly corresponds with a subtle photofeature, ground recovered as a small cluster of spindly gums on a patch of pisolitic and quartz-gritty, tan silty soil with scattered outcrops of ferruginous quartz sandstone/grit.

DAEDALUS feature 2/3/6

This feature was ground recovered as a bouldery outcrop knoll of densely silcreted saccharoidal quartz sandstone.

DAEDALUS feature 2/4/7

The DAEDALUS anomaly corresponds with a subtle photofeature, ground recovered as a relatively dense stand of timber on a low rise of pisolitic sandy soil with float clasts of ferruginous sandstone.
Loam sample 1084826 from the feature was reported negative for kimberlitic indicator minerals and microdiamonds.

A ground magnetometer traverse across the feature in field season 1986 (Colliver & Bubner, 1986; plan 'Figure 1') shows a very broad (wavelength 600m) dipolar response of ~10nT amplitude, consistent with subtle long-wavelength background responses observed in the airborne data.

In field season 1987, three north-south traverses were completed to enable a more definitive assessment of a short-wavelength 20nT response at 1000mN, recognised in the 1986 traverse 1000mE profile.
In addition to typical 'background clutter' variations of <5nT superimposed on part of a long-wavelength low-amplitude regional dipolar feature, profiles of these traverses (plan NTd 4560) show a 30nT vaguely-dipolar anomaly at 1000mN on line 1000mE, and short-wavelength responses of amplitude 10-20nT between 900mN and 1000mN on line 1100mE. These responses, and the 20nT response profiled by 1986 data, are considered due to a surficial or near-surface source - most likely magnetic pisolites and/or weakly magnetic ferruginous sandstone.

DAEDALUS feature 3/2/8

The DAEDALUS anomaly corresponds with a subtle phototone feature, ground recovered as a low rise of pisolitic soil with scattered rubbly subcrop of lateritised (Cretaceous?) sandstone.

In field season 1987, 7.5 kilometres of ground magnetic traversing was completed on two east-west and five north-south lines. The profiles (plan NTd 4472) are dominated by relatively smooth dipolar responses of amplitude 100-200nT. Wavelengths are consistently of the order of 150 metres, suggesting source depths of approximately 50 metres.

Location of the DAEDALUS feature is in a zone of disturbed aeromagnetics interpreted to be caused by Seisal Volcanics (plan Ntd 4019) and ground survey profiles are entirely consistent with this interpretation: in this context, there is no discrete magnetic response correlative with the DAEDALUS feature.

DAEDALUS feature 4/3/14

This feature was ground recovered as a well defined vegetation anomaly of relatively sparse scrub on red sandy soil. The feature is located on the southern margin of a magnetically complex zone, caused by a belt of interpreted volcanics.

A ground magnetometer traverse across the feature in field season 1986 (Colliver & Bubner, 1986; plan "Figure 2") displays a steeply descending gradient south of 1100mN, interpreted to correspond with the edge of the volcanics sheet. A 25nT dipole observed also on the profile is near-coincident with line section 1050-1350mN, corresponding with the DAEDALUS/photofeature confines.

Loam sample 1084833 from the feature was reported negative for kimberlitic indicator minerals and microdiamonds.

To check the possibility that the 25nT anomaly could be caused by a discrete source, and masked in the airborne data by responses of a sub-surface sheet of Tawallah Group volcanics, additional ground magnetometer traverses were undertaken in field season 1987.
The ground magnetic anomaly was confirmed as a 70nT dipole, centred at 880mE 1250mN (plan NTd 4561), with an indicated source depth of ~50 metres.

The interpreted source depth and regional aeromagnetic setting suggest Tawallah Group volcanics as the probable source of the magnetic anomaly. However, the coincidence of DAEDALUS and magnetic anomalies was considered to warrant subsurface investigation (see section 7.2 of this report).

DAEDALUS feature 4/4/15

The DAEDALUS anomaly corresponds with a dark phototone feature, ground recovered as a low rise of abundantly pisolitic red-brown sandy soil with scattered float rubble of laterite and ferruginous sandstone. Silcreted white quartz sandstone crops out on the creek bank, south of the feature. To the north, pisolites become much less abundant, in khaki sandy soil.

The profile of a single ground magnetometer traverse across the feature (plan NTd 4562) shows a broad 30nT high, representing a section of one of numerous broad, low-amplitude, deep-source "background" aeromagnetic features of a major zone of disturbed aeromagnetics due to Tawallah Group volcanics at depth.
There is no discrete magnetic anomaly corresponding with line section 1050-1700mN, across the DAEDALUS/photo-feature.

DAEDALUS feature 4/4/16

The corresponding dark phototone feature was recovered as an area of grey-tan sandy soil, relatively darker than its surrounds and with more abundant pisolites.

The ground magnetic data profile of a traverse across the feature (plan NTd 4563) shows a gradient rising to the north, representing a section of a long-wavelength 'background' aeromagnetic feature.
There is no discrete magnetic anomaly corresponding with line section 1100-1700mN, over the DAEDALUS/photo-feature.

Loam sample 1084831 from the feature was reported negative for kimberlitic indicator minerals and microdiamonds.

DAEDALUS feature 4/5/17

This feature was ground recovered as a well defined vegetation anomaly of dense scrubby timber on ferruginous sandy soil.

A ground magnetic profile across the feature (plan NTd 4564) is essentially devoid of any relief.

DAEDALUS feature 5/4/19

This feature was ground recovered as a densely timbered knoll of rubbly subcrop of heavily ferruginised 'doleritic' volcanic rock, flanked to the northeast by subcrop of lateritised (Cretaceous?) sandy mudstone.

One E-W and two N-S ground magnetometer traverses, totalling 2.4 line-km were surveyed over this feature in field season 1986 (Colliver & Bubner, 1986; plan 'fisure 6').
Profile sections 800-1000mE on line 1000mN and 950-1300mN on line 900mE, across the knoll, show a slight increase in noise levels (~10nT, compared with a background of <5nT). Other than this, there is no discrete magnetic response coincident with the DAEDALUS feature.
[A 50nT dipole on line 1000mE, centred at ~1330mN (northeast of the knoll) was confirmed subsequently from the aero-magnetic data as a 7nT dipole in relative isolation on flight line 1451.]

Loam sample 1312088 was taken at about 1000mE 920mN, from a drainage 'pan' collecting runoff from the knoll area.
Kimberlitic indicator mineral and microdiamond reports were negative.

Rock sample 1312089 of the 'doleritic' rock was collected at about 900mE 1050mN.
Geochemical analysis gave a signature suggestive of identification as a heavily ferruginised basic igneous rock of syenitic association (Appendix 4).
From thin-section examination, the rock was identified as a weathered ferruginised quartz microgabbro (Appendix 4).

In field season 1987, five additional traverses totalling 2.2 line-km were undertaken to investigate the dipolar response centred at 1000mE 1330mN.
The profiles from the northern part of the grid (plan NTd 4565) are dominated by single-reading noise spikes of hundreds nT's amplitude, with no 'real' response discernable. The source of the ground magnetic and aeromagnetic anomaly is considered to be highly magnetic ferruginous gravels observed in this part of the grid area.

DAEDALUS feature 5/4/20

The DAEDALUS anomaly corresponds with a subtle photo-tone feature, ground recovered as a patch of relatively dense low scrub on loose ashy-grey-tan silty soil. A more prominent photofeature close to the southwest is a sparsely timbered, pisolitic 'hardpan' area with scattered rubbly subcrop of lateritised (Cretaceous?) sandstone/sandy mudstone.

Ground investigation in field season 1986 included three magnetometer traverses totalling 2.2 line-km.
Profiles are shown in plan NTd 4566.
The DAEDALUS feature was traversed by line section 1650mE 1300-1500mN. The magnetic profile shows relatively smooth variations of a few nT, with no discrete magnetic anomaly.
The profile of line 1000mE, centred on the 'hardpan', is dominated by single reading noise spikes up to 160nT amplitude from 600mN to 1350mN. This is consistent with observed pisolite accumulations and lateritised sandstone rubble which gave magnetic susceptibility readings up to 0.008 SI units.

Loam sample 1312090, taken on the pisolitic pan at about 1000mE 970-1020mN, was reported negative for kimberlitic indicator minerals and microdiamonds.

DAEDALUS feature 5/5/21

The DAEDALUS anomaly corresponds with a vegetation photo-anomaly, ground recovered as a patch of dense scrubby timber on a hill capping of (Cretaceous?) ferruginous sandstone.

DAEDALUS feature 5/5/22

This feature corresponds with a subtle photoanomaly, identified from the helicopter to correspond with a patch of locally darker soil and a ring of trees.

DAEDALUS feature 5/5/23

This feature corresponds with a vegetation and soil tone photoanomaly, ground recovered as an area of large paperbarks, pandanus clumps and heavy grass cover on a swampy "soak". Scintillometer readings up to ~70cps (BGS 2) were observed.

Other photofeatures

Loam samples 1312217-220 were collected in field season 1987 from subtle photofeatures (not previously selected for investigation) in the Snake Creek headwaters area.

Sample locations are shown on plan NTd 4020;
No kimberlitic indicator minerals or microdiamonds were reported in these samples.

7.2 Bedrock Auger Sampling

A program of bedrock auger sampling was undertaken in field season 1987, to investigate suboutcrop geology of aeromagnetic anomalies SNC 1, SNC 2 and SNC 5 and of DAEDALUS/photofeatures 2/4/7, 3/2/8, 4/3/14 and 5/4/20.

A Gemcodrill HT-7 mounted on a Chamberlain Champion Industrial Mark 4 tractor was utilised, with a 10cm diameter flighted auger rod string and tungsten carbide tipped hard formation bit.
Fences of holes were drilled at 50m to 100m centres on selected line sections of the ground survey local grids, traversing the positions of indicated shallow magnetic sources.
Holes were sunk to identifiable weathered bedrock, or until effective penetration limit was reached.
Bottom-hole cuttings samples bulking about 10kg were taken for kimberlitic indicator mineral observation by the CRAE Belmont laboratory, with a representative split taken off for geochemical analysis. A Kraft packet of representative larger chips was also collected for logging of bedrock lithology.

Gemcodrill auger cuttings logs are included in Appendix 5.
Indicator mineral sample data are tabulated in Appendix 3, for samples keyed on the Gemcodrill logs.
Geochemical analysis reports are included in Appendix 4.

Aeromagnetic anomaly SNC 1

To investigate suboutcrop geology of the area of the indicated magnetic source, local grid line 1100mE was auger drilled at 50m centres 650-850mN and 1000-1800mN.

Cuttings logs record 1-5m of ferruginous sand, nodular laterite and ferruginous sandstone, with felspathic sandstone chips recovered at the bottoms of holes. Depths >5m were reached only south of 750mN and at 1300mN.
Magnetic susceptibilities of 0.001-0.008 SI units were measured for bottom-hole cuttings samples from line sections 1100-1350mN and 1500-1750mN.

Single microdiamonds were reported in each of cuttings samples 1312340 (local grid 1100mE 1100mN; surface to 2.4m) and 1312346 (1100mE 1500mN; surface to 0.9m); and two microdiamonds in sample 1312347 (1100mE 1550mN; surface to 1.0m).
No other kimberlitic indicator minerals were detected.
No signature suggestive of kimberlitic lithology was recognised in geochemical analysis reports for cuttings split samples 1312337, 1312339, 1312343, 1312345 and 1312349.

Aeromagnetic anomaly SNC 2

To investigate suboutcrop geology of the area of the anomaly centre, local grid line 1000mE was auger drilled at 50-75m centres 550-1050mN.

Cuttings logs record superficial ferruginous sandy soil and lateritic gravel, underlain by fine-grained felspathic sandstone to the limit of penetration by the auger at ~5m.
Magnetic susceptibilities of ~0.0005 SI units were measured for bottom-hole cuttings samples.

One microdiamond was reported in cuttings sample 1312333 (local grid 1000mE 550mN; 2-2.4m); kimberlitic indicator and microdiamond reports were otherwise negative.
No signature suggestive of kimberlitic lithology was recognised in geochemical analysis reports for cuttings split samples 1312327-331.

Aeromagnetic anomaly SNC 5

To investigate suboutcrop geology of the magnetic anomaly source area, local grid line 1100mE was auger drilled at 50-100m centres 800-1450mN.

Cuttings logs record generally 10-15m of red sand, with lateritic rubble and ferruginous sandstone in places. Weathered "doleritic" volcanic lithologies were logged in bottom-hole cuttings from all holes deeper than ~15m and as shallow as 8m at 900mN.
Magnetic susceptibilities of 0.00025-0.007 SI units were measured for bottom-hole cuttings samples.

No kimberlitic indicator minerals or microdiamonds were reported in cuttings samples.
No signature suggestive of kimberlitic lithology was recognised in geochemical analysis reports for cuttings split samples 1312301-303 and 1312307-308.

DAEDALUS feature 2/4/7

To investigate suboutcrop geology of this subtle photo-feature, located only about 2km east of aeromagnetic anomaly SNC 1, local grid line 1000mE was auger drilled at 50m centres 900-1100mN.

Cuttings logs record superficial sand and lateritic gravel, underlain by lateritized quartz-gritty felspathic sandstone to the limit of penetration by the auger at depths 2.4-7.4m.
Magnetic susceptibilities of 0.0003-0.0005 SI units were measured for the relatively deeper bottom-hole cuttings samples; laterite/lateritized sandstone cuttings sample 1312360, from 1000mN (surface-2.4m) gave a reading of 0.002 SI.

One microdiamond was reported in cuttings sample 1312362 (local grid 1000mE 1100mN; 4-6.1m); kimberlitic indicator and microdiamond reports were otherwise negative.
No signature suggestive of kimberlitic lithology was recognised in geochemical analysis reports for cuttings split samples 1312359-361.

DAEDALUS feature 3/2/8

To investigate suboutcrop geology of this subtle photofeature, local grid line 1170mE was auger drilled at 50m centres 1300-1500mN and at 1600mN.

Cuttings logs record superficial ferruginous sandy soil, underlain by lateritized felspathic sandstone to the limit of penetration by the auger at depths of 4.9-7.3m.
Magnetic susceptibilities of 0.0002-0.0008 SI units were measured for bottom-hole cuttings samples.

No kimberlitic indicator minerals or microdiamonds were reported in cuttings samples.
No signature suggestive of kimberlitic lithology was recognised in geochemical analysis reports for cuttings split samples 1312321-322.

DAEDALUS feature 4/3/14

To investigate suboutcrop geology of this photofeature with coincident dipolar magnetic anomaly, local grid line 880mE was auger drilled at 50m centres 1000-1400mN.

Cuttings logs record generally ~5m (>12m at 1400mN) of red sand, underlain by ferruginous sandstone and fine grained to gritty and quartzite-pebbly felspathic sandstone (probably of the Westmoreland Conglomerate). Penetration limit was reached at depths of 2.4-15.3m.
Magnetic susceptibilities of 0.0001-0.0006 SI units were measured for bottom-hole cuttings samples.

No kimberlitic indicator minerals or microdiamonds were reported in cuttings samples.
No signature suggestive of kimberlitic lithology was recognised in geochemical analysis reports for cuttings split samples 1312312-316.

DAEDALUS feature 5/4/20

To investigate suboutcrop geology of the pisolitic hardpan photofeature, local grid line 1000mE was auger drilled at 50-100m centres 800-1200mN.

The auger achieved penetrations of 1-5m only, into lateritized conglomeratic(?) sandstone.
Magnetic susceptibilities of 0.0004-.0065 SI units were measured for bottom-hole cuttings samples.

No kimberlitic indicator minerals or microdiamonds were reported in cuttings samples.
No signature suggestive of kimberlitic lithology was recognised in geochemical analysis reports for cuttings split samples 1312365 and 1312367-368.

A PROGRAM IN THE GASP SYSTEM TO
PRINT A LISTING OF A DATA SET

VERSION 4.0 AUG 1983.

DATA TITLE: McARTHUR BASIN SAMPLING/I.M. RESULTS 1983-85

LISTING OF ARCHIVAL INFORMATION FOR THE INPUT DATA

SOUTH NICHOLSON BASIN RECONNAISSANCE SAMPLING

SAMPLE NOs. 1080679, 680
1080683 - 1081300
1081306 - 326
DPO NOs. 21395, 21396
PERSONNEL: I.C.Colliver, D.A.Sims, B.E.Harvey
Reconnaissance drainage gravel sampling program,
aimed at a sampling density of about 1 : 20km2
Trap site selection and sample collection helicopter supported
Drainage samples sieved -2mm (generally 1 x 20kg bag per site)
Kraft packet -80mesh geochemical sample sieved on site from
active drainage sediment

CALVERT AREA INFILL/FOLLOW-UP AND RECONNAISSANCE EXTENSION

SAMPLE NOs. 1081327 - 1081341 (Karns infill/follow-up)
1081342 - 1081600 |
1081617 - 638 | (Reconnaissance infill
1081640 | and extension)
1081642 - 687 |
1081691 - 696 |
DPO NOs. 21397, 21398
PERSONNEL: I.C.Colliver, D.A.Sims, K.R.Alexander
Follow-up of positive results of reconnaissance sampling,
infill drainage sampling (aimed at increasing sample density
to about 1 : 12km2) and extension of coverage area
of reconnaissance drainage samplings
Trap site selection and sample collection helicopter supported
Drainage samples sieved -2mm (generally 1 x 20kg bag per site)
Kraft packet -80mesh geochemical sample sieved on site from
active drainage sediment

CALVERT RIVER CAMP 3/1985 FOLLOW-UP SAMPLING (September)

SAMPLE NOs. (1084785, 1084786 DPO 22026 geochem)
1084787 - 1084834 DPO,s 22023, 22024
PERSONNEL: I.C.Colliver, G.J.Bubner, J.H.Lew
Follow-up of positive results of previous drainage sampling in areas of EL's 1991, 4166 and ELA's 4496, 4504, and 4648
Selective 'loam' and rock chip sampling of ground recovered magnetic and radiometric airborne survey anomalies, DAEDALUS and airphoto features
Airborne geophysical survey anomaly, DAEDALUS feature and photofeature recovery, drainage trap site selection and sample collection helicopter supported
Loam samples composited of 5 bags of (-2mm) surficial soil, shallowly scraped over an area of several m2
Drainage samples sieved -2mm (1-5 x 20 kg bags per site)
Kraft packet -80mesh geochemical sample sieved on site from active drainage sediment

37610 (geochem), 37611 (petrology)
PERSONNEL: I.C.Colliver, B.J.Mayers
Follow-up of positive results of previous drainage sampling
Selective "loam" and rock chip sampling of ground recovered
aeromagnetic anomalies, DAEDALUS and airphoto features
Airborne geophysical survey anomaly, DAEDALUS feature and
photofeature recovery, drainage trap site selection and
sample collection helicopter supported
Loam samples composited of 2-5 bags (-2mm) surficial soil,
shallowly scraped over an area of several m2
Drainage samples sieved -2mm (2-5 x 20 kg bags per site)
Kraft packet -80mesh geochemical sample sieved on site
from active drainage sediment

HORSE CREEK CAMP 1/1987 SAMPLING PROGRAM (April-May)
incl. SNAKE CREEK GEMCO AUGER SAMPLING

SAMPLE NOs. 1312031 - 1312050
1312174 - 300
DPO NOs. 37624-37626

SAMPLE NOs. 1312301 - 1312311 [Gemco] SNC 5
1312312 - 320 3/4/14
1312321 - 326 3/2/8
1312327 - 335 SNC 2
1312336 - 357 SNC 1
1312358 - 362 2/4/7
1312363 - 369 5/4/20
DPO NOs. 37624, (37627 geochem)

PERSONNEL: I.C.Colliver, E.R.Manning, A.J.Hawthorne

Follow-up of positive results of previous exploration in the EL 1991 and EL 4989 areas, plus extension of reconnaissance drainage gravel sampling over the EL 4990 area
Airborne geophysical survey anomaly, DAEDALUS feature and photofeature recovery, drainage trap site selection and sample collection helicopter supported
Drainage samples sieved -2mm (1-5 x 20kg bags per site)
Kraft packet -80mesh geochemical sample sieved on site from active drainage sediment
Loam samples composited of 2-5 bags (-2mm) surficial soil, shallowly scraped over an area of several m2

Follow-up investigation of selected aeromagnetic anomalies and photofeatures by bedrock auger sampling on local grid lines of the ground magnetic surveys
Gemcodrill HT-7 operation, field logging and sampling supervision by G.R.Collins & M.Tudehope
Samples collected each comprise 1 bag (~20 kg) bottom-hole cuttings plus a Kraft packet of representative larger chips for identification of bedrock lithology
(Geochemical samples selectively split off cuttings samples)

LABELS LEGEND

EAST	A.M.G. coordinates (km) including zone
NORTH	
SAMTYPE	SAMPLE TYPE coded 1 = drainage (1.2 = pan con.) 2 = loam 3 = rock 3.1 = outcrop 3.2 = float 3.3 = auger cuttings 3.4 = RD/PD 3.5 = DD core
SAMKG	SAMPLE WEIGHT (kg)
IND1	KIMBERLITIC INDICATOR MINERAL GRAINS OBSERVED (1.CR = 1 chromite)
IND2	INDICATOR MINERAL #2 OR OTHER MINERAL OF INTEREST
MICROD	NUMBER OF MICRODIAMONDS RECOVERED

IDENTIFICATION
1312089
Weathered, Ferruginised Quartz Microgabbro

Job No. CMS 86/7/3 Date Received: 3.7.1986

Reference D.P.O. No. 37611

Sample No. 1312089

Nature of Sample: Hand Specimen

DESCRIPTION **SECTION No.** 56189

a. **Hand Specimen:**

Dark brown ferruginised, medium-grained ?igneous rock.

b. **Microscopic:**

This rock reflects marked weathering and secondary ferruginisation, but may be classified as a quartz microgabbro on the basis of relict textural and compositional features.

The rock consists essentially of limonite and optically ill-defined limonite-stained clays. Quartz is disseminated throughout and represents a primary phase defining a siliceous mesostasis, locally subgraphic with included (degraded, ferruginised) feldspar microlaths. Limonite and limonitic clays are extensively pseudomorphous after medium-grained feldspar laths and subordinate lath-like to subophitic pyroxene. Disseminated ovoid to irregular limonite clots represent degraded ?chloritic amygdales. Primary accessory magnetite is represented by hematitic ("martite") pseudomorphs.

Feldspar was clearly extensively phyllosilicate-altered prior to the secondary (weathering-induced) ferruginisation, and there is some microtextural evidence of pyroxene-replacive amphibole development ("uralitisation").

On the basis of relict textural features, this rock appears to represent a sub- to marginal (amygdaloidal) felsic-differentiated (siliceous-mesostasised) intrusive phase.

OUR REF : 15.8.01.44924
YOUR REF : DPO 37610
ATTENTION: Mr I. Colliver

Dear Sir

Herewith the results of the whole rock analysis of samples covered by the above DPO.

Because of the large amount of work passing through our ICP at this time we have changed the methods used to that of XRF so that we can maintain a smooth output of results for you. We realise that on a cost basis the XRF analysis for trace elements is more expensive than ICP and as a consequence have discounted the XRF trace work at 50%.

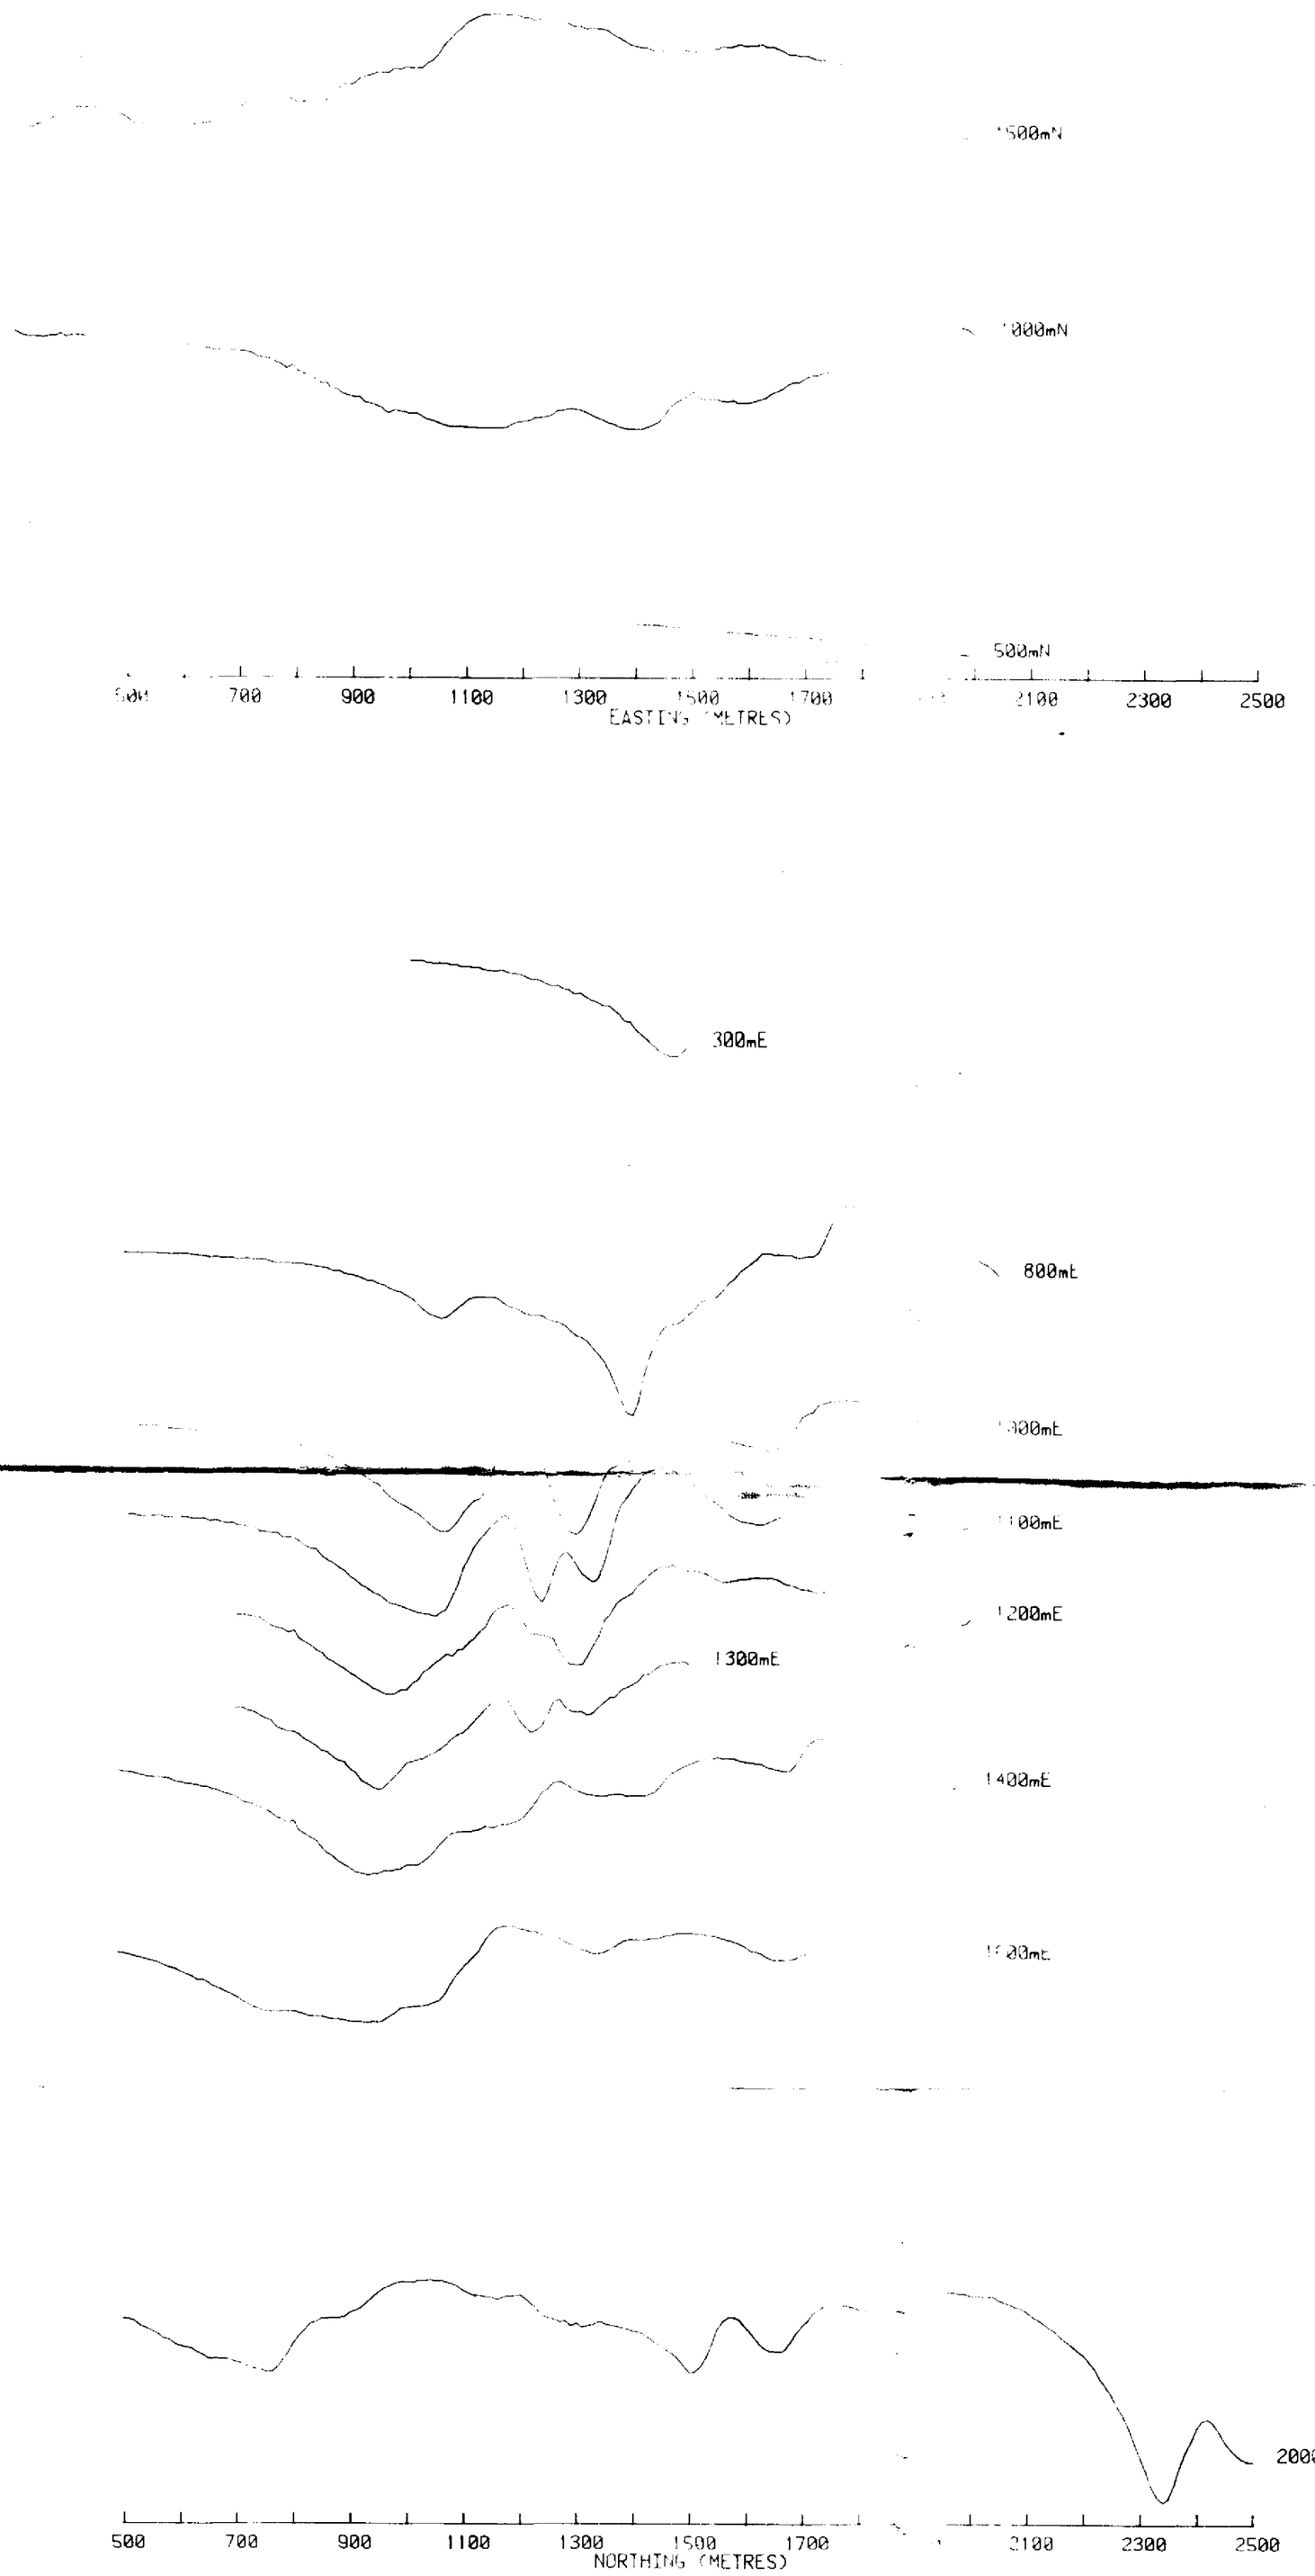
GEMCODRILL AUGER LOGS

A'mas anomalies SNC 1, SNC 2 & SNC 5,
Features 2/4/7, 3/2/8, 4/3/14 & 5/4/20



Airborne survey : SNAKE CREEK
Date flown : JUNE 1984
Sheet reference : SNC8

1:100 000 Sheet : NICHOLSON RIVER 636

Magnetometer : MP3 #403208,507263
Sensitivity : +/-0.2 nT
Sensor height : 2 metres
Diurnal correction applied
Base station mag: MP3 #403208;403229

Grid north : 000 MAGNETIC
Station spacing : 10 metres
Survey date : SEP85;09,13-06-86
Operator : JL;ICC,BJM

Scale-horizontal: 1:10000
-vertical : 50 nT/CM

		4	5·3	As above, to fresh SST.	Lateritised sandstone?	1312322	4	5·3	24	70	
1170E	1400N	0	2	Ferruginous SST. & latentic gravel.							
		2	4	Light brown weathered SST.							
		4	5·3	Weathered SST. — hard bottom.	Latentic material + loose qz. sand & feldspar grains	1312323	4	5·3	80	70	
1170E	1450N	0	2.	Ferruginous SST, latentic gravel & weathered SST.							
		2	4.	Brick red cuttings: weathered SST.							
		4	6	Light brown weathered SST.							
		6	7·3	As above to buff-white chips of feldspathic sandstone.	Poorly sorted coarse-grained feldspathic sandstone.	1312324	6	7·3	20	60	
1170E	1500N	0	2	Ferruginous sandstone, laterite gravel & weathered SST.							
		2	4	Light brown cuttings: chips of weathered SST.							
		4	5·3	Weathered to fresh feldspathic SST.	Feldspathic SST., F–M, slightly ferruginous.	1312325	4	5·3	20	65	
1170E	1600N	0	2	Mustard yellow to light brown sand.							
		2	4	Light brown cuttings: weathered SST chips.							
		4	6	As above + yellow clay.							
		6	6·4	Beige cuttings & clay — SST.	SST. as above.	1312326	4	6·4	–	–	

SUMMARY AND SPECIAL COMMENTS: All holes appear to terminate in feldspathic sandstone or laterite / lateritised sandstone. Drilling discontinued.
