SUMMARY

During the period 24th May, 1994 to 23rd May, 1995 Ashton Mining Limited, on behalf of the Australian Diamond Exploration Joint Venture (ADE JV), carried out an exploration programme over Exploration Licences 7260, 7261, 7262, 7263, 7264 and 7341. This report provides details of work undertaken on the Nathan River Project tenements during the reporting period.

Exploration activities conducted by Ashton Mining Limited, comprised reconnaissance gravel and loam sampling. A total of sixty-three samples were collected in these programmes, and forwarded to Ashton's Perth laboratory for analysis. Positive diamond results were identified in samples taken from ELs 7263, 7264 and 7341, however laboratory processing is yet to be completed.

BHP Minerals have two concurrent exploration programmes operating on these tenements; manganese, which concluded at the end of 1994, and base metals, which is continuing. These programmes have been reported as separate sections in this report.

Exploration for base metals comprised ground TEM, soil and rock geochemical sampling, percussion and diamond drilling and the reinterpretation of a QUESTEM airborne TEM survey. Exploration for manganese comprised extensive percussion drilling, diamond drilling and downhole EM surveying.

(ii)

Exploration expenditure for the reporting period amounted to \$ 799,982 against a combined covenant of \$ 278,700.

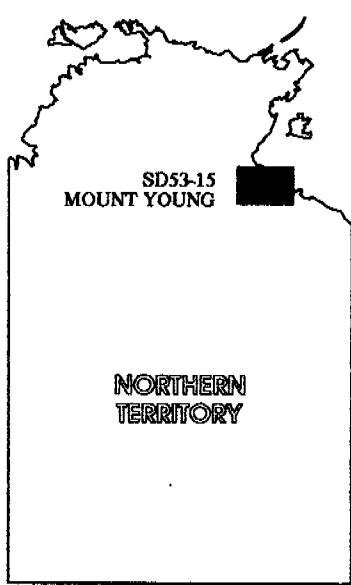

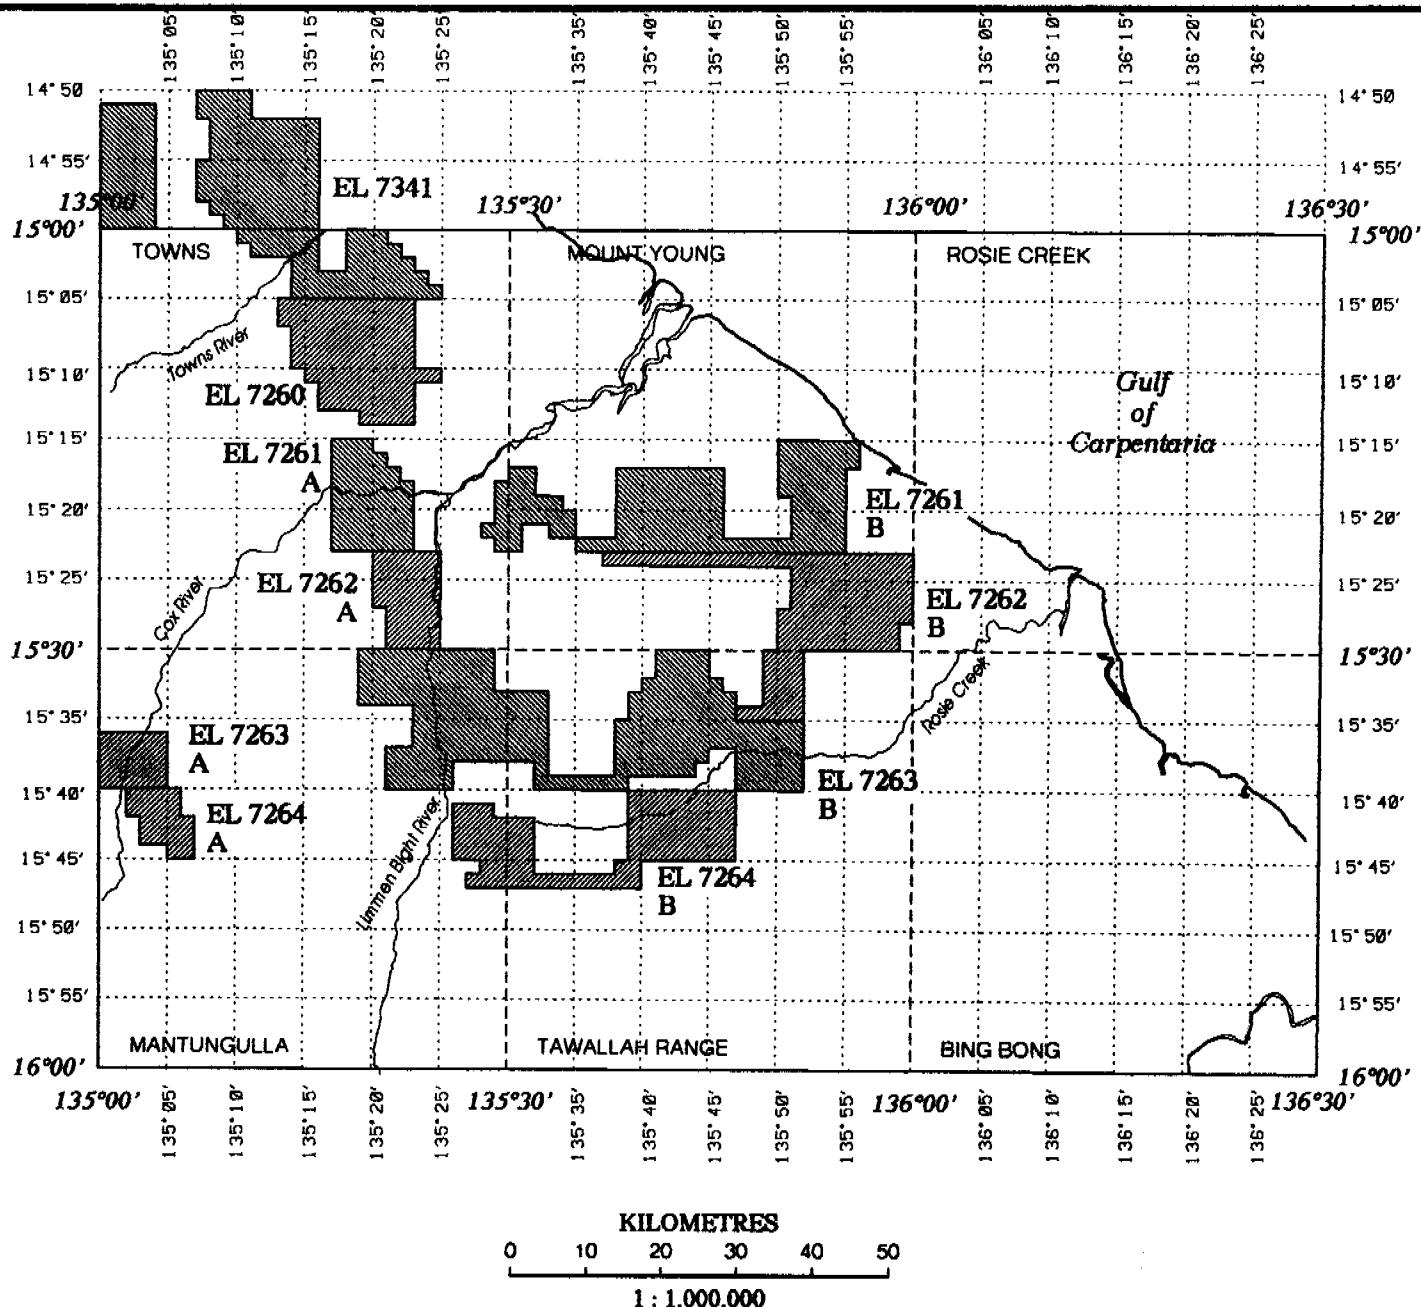

1.0 INTRODUCTION

Exploration Licences 7260, 7261, 7262, 7263, 7264 and 7341 were granted to Ashton Mining Limited in 1991, for a period of six years (see Table 1). Ashton Mining Limited is manager of the licences, on behalf of the Australian Diamond Exploration Joint Venture (ADEJV). Participants of the ADE Joint Venture also include Aberfoyle Resources and Australian Diamond Exploration Pty Ltd (ADEX).

The licences cover a combined area of 825 blocks and are located on the Mt Young (SD 53-15) and Roper River (SD 53-11) 1:250,000 map sheets. Tenement location maps are shown in Figure 1. Group reporting was requested on the 20th January, 1993 and approved by the Department of Mines & Energy in February 1993. These tenements are referred to as the Nathan River Project tenements.

TABLE 1.
NATHAN RIVER PROJECT TENEMENTS

Tenements	Date Granted	Area (blocks)	Expenditure Commitment
EL 7260	06/06/91	75	51,800

LOCATION MAP**

JUNE, 1995

On the 24th January, 1992, Ashton Mining Limited entered into a joint venture agreement with BHP Minerals Pty Ltd which would allow BHP to earn up to 80% of the base metal rights to these tenements. The joint venture is known as the McArthur River Joint Venture.

This report provides a summary of work undertaken, both by Ashton Mining and BHP Minerals, during the reporting period 24th May, 1994 to 23rd May, 1995. A statement of expenditure for each licence is included in this report.

2.0 EXPLORATION PROGRAMME

2.1 Reconnaissance Stream Sampling

A reconnaissance stream sampling programme was completed over ELs 7260, 7262, 7263, 7264 and 7341, during the fourth year of tenure. A total of fifty-six, 2 bag stream samples were collected and forwarded to Ashton's Perth laboratory for analysis (*see Section 2.3*). Two samples returned a positive result, both containing one microdiamond. Laboratory processing is still to be completed.

Sample locations are shown on Plans 1 to 5. A complete listing of sample results is given in Appendix 1.

2.2 Reconnaissance Loam Sampling

Reconnaissance loam sampling was undertaken within ELs 7260 and 7341. A total of seven, 5 bag samples were collected and forwarded to Ashton's Perth laboratory for analysis (*see Section 2.3*). Three samples reported positive, each containing one microdiamond.

Sample locations are shown on Plans 1 and 5. A complete listing of sample results is given in Appendix 1.

2.3 Laboratory Procedure

All samples were processed by the Ashton Mining Limited Laboratory in Perth, where they were concentrated by Wilfley Table and heavy liquid separation techniques.

The heavy liquid used was tetrabromethane with a specific gravity of 2.96. The concentrates were then screened into various size fractions, further concentrated by magnetic and electrostatic separation techniques and a comprehensive grain by grain examination carried out on the minus 1.0mm plus 0.425mm fractions.

3.0 BHP EXPLORATION PROGRAMME

I. Base Metal Exploration

3.1 Geophysics

3.1.1 QUESTEM Anomaly Follow-Up

Nine anomalies from a QUESTEM survey flown in the Nathan River area by BHP in June 1992 were followed up with ground TEM in 1994. Anomaly selection was based on stratigraphic and structural grounds, and electrical characteristics. Anomaly details are given in Table 2, locations in Plate 1 and survey logistics in Table 3. Data are presented as profiles (moving loop) and apparent resistivity vs time curves (soundings) in Appendix 2.

MY6 AND MY9

Anomalies MY6 and MY9 are thought to be caused by an extensive saline water table within Proterozoic lithologies. It is characterised by a thick, moderate to highly conductive layer (<20 Ωm) at both sites. The layer is observed to dip gently to the west.

MY7

Computer inversion of soundings data from site MY7 reveals a westerly dipping conductive unit of average conductance 10 S.

MY10

Moving loop PROTEM data collected at site MY10 indicate that the observed anomalous response can be attributed to conductive sediments (up to 20 S) associated with the tidal Limmen Bight River. The eastern end of the profile in fact is terminated by the river.

MY11

Data collected at anomaly MY11 confirm the airborne TEM feature to be a shallow, west dipping conductor of low to moderate conductance (2 - 5 S).

MY13

Ground TEM detailing of MY13 clearly highlights an easterly dipping conductor with apparent resistivities ranging between 20 and 30 Ω m. The response on the northernmost profile is complicated by its proximity to the Limmen Bight River, as was the case at site MY10.

MY16

At site MY16, TEM profiling confirms the existence of west dipping conductive stratigraphy. These data are similar to those collected at site MY13.

MY17

Anomaly MY17 is identified in the ground data as a moderately conductive, east dipping unit ranging in thickness from 200 to 350 m. The most likely source is Roper Group stratigraphy.

MY21

A clearly defined east dipping conductor is highlighted at anomaly MY21. The conductor has remarkable consistency down dip, with apparent resistivities of between 11 and 14 Ωm .

3.1.2 QUESTEM Survey Reinterpretation

A detailed reinterpretation of BHP's 1992 Mount Young QUESTEM airborne TEM survey has been undertaken. The survey covers large portions of the Nathan River Project tenements. Anomaly selection was based primarily on stratigraphic and structural considerations, with new anomalies having a lower conductance than those chosen in the previous interpretations. A total of eleven anomalies were selected for ground follow-up during the 1995 field season. Anomaly details are given in Table 4.

Ground TEM follow-up commenced in mid-May 1995. Results will be reported in the next annual report.

3.2.3 Mount Young TEM Soundings

A 22 site PROTEM TEM sounding program was completed on E7262. The sites were located on seven east-west lines, giving a square grid configuration with a grid-based spacing of 1.6 km. The area is located at the eastern edge of E7262, and is to the east of a grid-based soundings program completed in 1993.

Site locations are presented in Plate 1, coordinates are given in Table 5, survey logistics in Table 6, and the data are displayed graphically as apparent resistivity vs time plots in Appendix 3.

Soundings were employed as a means of detecting bedrock conductors possibly related to base metal mineralisation in areas where the prospective Proterozoic units are covered by younger sediments. The site locations were planned using an aeromagnetic data interpretation, which delineated favourable structures in the Proterozoic units.

All the soundings indicate the presence of a very conductive surficial layer (2-17 Ω m), reaching a maximum thickness of approximately 90 m, but commonly around 50 m thick. This layer is thought to represent mudstones/claystones of Cretaceous age.

Electrical responses of the underlying Proterozoic units are variable, with resistivities ranging from 24 Ω m to more than 1000 Ω m. A group of four soundings on the western side of the grid show a conductive layer in the Proterozoic. This layer is interpreted to represent Caranbirini Member of the Lynott Formation.

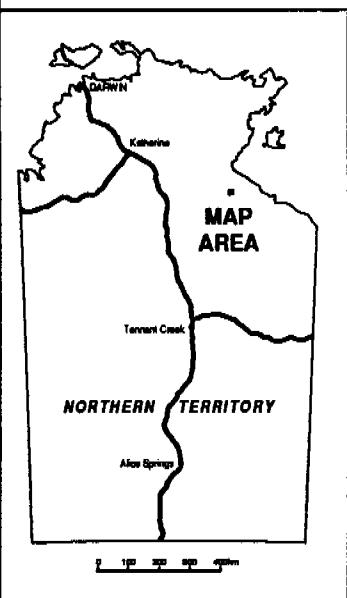

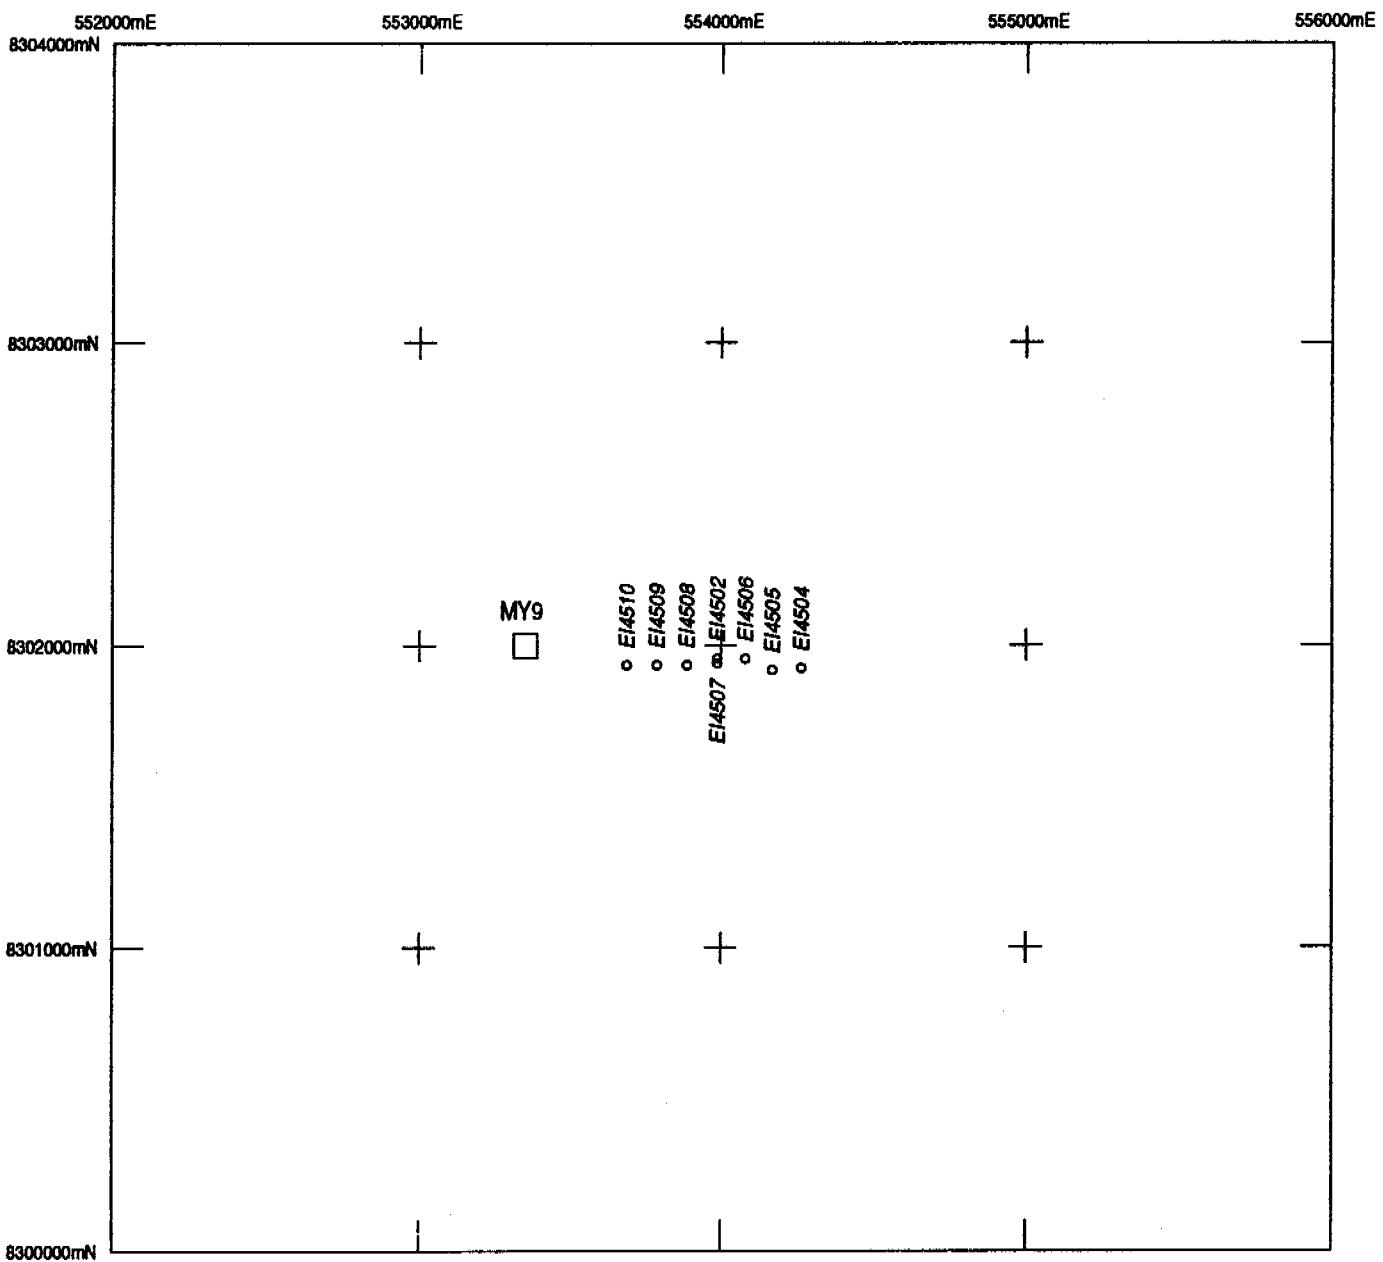

The most anomalous response identified is in sounding Y292/018, which highlights a 24 Ωm layer between approximately 35 m and 145 m depth. It is planned in the 1995 field season to conduct a further seven soundings to map the western extent of this layer, possibly followed by drill testing if strong conductors are identified.

3.2 Geochemistry

3.2.1 QUESTEM Anomaly Soil Sampling

Four anomalies, MY19, MY26/28 and MY29, were followed up solely by soil geochemistry. These shallow anomalies occurred in moderately dipping Roper Group stratigraphy where the conductive horizon could reasonably be expected to outcrop or subcrop. Two further anomalies, MY9 and MY17, had one line of soil sampling completed in addition to ground TEM. Approximately 100 grams of -80 mesh fraction was sieved at each sample site. Table 7 gives details of the sampling. Locations are plotted in Figure 2, and Plates 2 and 3. Samples were submitted to Analabs Pty Ltd, Townsville, QLD for analysis. Analytical procedures and results are given in Appendix 4.

Assay results are not considered anomalous for any of the anomalies with peak values of only 25 ppm Cu, 12 ppm Pb and 33 ppm Zn. While the exact cause of these anomalies remains unknown, it is not considered to be related to significant base metal mineralisation.

3.2.2 Rock Chip Sampling

A single rock chip sample was collected on E7261. The sample was a quartz vein. Analytical procedures and results are given in Appendix 4. The assay values are not considered anomalous.

3.3 Drilling

Two diamond and three RC percussion holes were drilled on the Nathan River Project during the 1994 field season. Drilling meterage totalled 552 m RC percussion and 118.2 m NQ core. Drilling was contracted to Gaden Drilling, Batchelor, NT. A Warman UDR650 drill rig was used for all holes. Drilling details are given in Table 8. Drill logs are presented in Appendix 5, and graphic summary logs in Plates 4, 5 and 6. Drill hole locations are plotted on Plate 1. Six metre, composite drill chip and third core samples were submitted to Analabs, Townsville, QLD for analysis. Analytical procedures and assays are presented in Appendix 6.

3.3.1 Percussion Drilling

MYP001

One percussion hole, MYP001 was drilled to a depth of 96 m on E7341 to test QUESTEM anomaly MY1. MYP001 intersected a weathered red, brown ferruginous mudstone from 0 to 18 m underlain by a ferruginous sandstone to 20 m. Red, brown ferruginous shales were intersected from 20 m to 55 m, followed by dark grey shales to 80 m. These shales are thought to be the conductive source at MY1. Sandstone with trace muscovite and shaley

interbeds were intersected from 80 m to 96 m. MYP001 is interpreted to have intersected Mantungula Formation at the base of the Roper Group. Assays are low with a peak value of 218 ppm Zn.

MYP002

One percussion hole, MYP002, was drilled to a depth of 98 m on E7262 to test QUESTEM anomaly MY11. MYP002 intersected a weathered laminated dolomitic siltstone from 1 to 22 m. This was underlain by a black, laminated carbonaceous dolomitic siltstone to 80 m which is thought to represent the conductive source at MY11. The conductive layer is underlain by red and grey dolomitic siltstone to 88 m and a red to grey fine sandstone to 98 m which corresponds reasonably well with a basement of $424 \Omega\text{m}$ in the TEM inversion. MYP002 is thought to have intersected Proterozoic Balbirini Dolomite of the Nathan Group. Assays are low with a peak value of 76 ppm Cu.

MYP004

One percussion hole, MYP004, was drilled to a depth of 118 m on E7263 to test QUESTEM anomaly MY21. MYP004 intersected a weathered laminated siltstone down to 16 m. This upper oxidised layer was underlain by grey, laminated carbonaceous dolomitic siltstones to 108 m which are thought to be responsible for the conductor at MY21. These rocks are underlain by a micaceous dolomitic fine sandstone from 108 to 118 m which is represented

quite well in the TEM inversion by a resistive basement of 220 Ωm. MYP004 intersected Proterozoic Mainoru Formation of the Roper Group. Assays are low with a peak value of 81 ppm Zn.

3.3.2 Diamond Drilling

MYD002

One diamond hole, MYD002, was drilled on E7263 to test QUESTEM anomaly MY24. MYD002 was pre-collared to 120 m by percussion drilling and completed to a final depth of 186.8 m by NQ diamond drilling.

MYD002 intersected highly weathered, laminated green, brown and red clayey mudstones from 0 to 30 m. From 30 to 78 m, brown and grey-green variably dolomitic mudstones were intersected , with minor fine pyrite at 62 to 64 m. MYD002 intersected dark green-grey to black, laminated, variably carbonaceous mudstones with minor quartz and carbonate veining from 78 to 182.3 m. Minor pyrite is present as fine disseminations and more commonly as blebs on fractures. Several chalcopyrite grains occur in a carbonate vein at 123 m. The underlying sequence from 182.3 to 186.8 m changes to interbedded green mudstones and fine sandstones, finishing in red-brown dolomitic mudstones with coarse silty interbeds.

The bedrock conductor at MY24 is explained by a sequence of laminated, carbonaceous mudstones. MYD002 is interpreted to have intersected the Proterozoic Mantungula Formation of the Roper Group. No anomalous base metal assays were returned.

MYD003

One diamond hole, MYD003, was drilled on E7261 to test QUESTEM anomaly MY7 (Plate 6). MYD003 was pre-collared to 120 m by percussion drilling and completed to a final depth of 171.4 m by NQ diamond drilling.

MYD003 intersected recent transported cover from 0 to 12 m, then Proterozoic mudstones with highly weathered clay horizons to 22 m. From 22 to 44 m a red-brown, laminated mudstone with minor green mudstone interbeds was intersected, underlain by interbedded light green to red-brown laminated mudstones and minor black carbonaceous mudstones to 78 m. From 78 to 161 m MYD003 intersected a sequence of dark green-grey to black, laminated, variably carbonaceous and micaceous mudstones with minor thin quartz sandstone interbeds at 144 to 151.4 m. These mudstones become less carbonaceous and change colour from black to a dark red-brown from 161 to 171.4 m.

The bedrock conductor at MY7 is explained by a sequence of laminated, carbonaceous and micaceous mudstones. MYD002 is interpreted to have intersected the Proterozoic Mantungula Formation of the Roper Group. No anomalous base metal assays were returned.

II. *Manganese Exploration*

3.4 Drilling

Gaden Drilling of Batchelor, N.T. were contracted to carry out the drilling. A UDR-650 multi-purpose drill rig mounted on a 6 x 6 truck was used. For the RC drilling most of the logging was done from two metre samples, but when mineralisation was seen the sample interval was reduced to a half or one metre. Diamond drilling consisted of PQ triple tube and was aimed at obtaining a better understanding of RC manganese intercepts. Therefore, all diamond holes were sited adjacent to RC holes with anomalous manganese.

Drill hole locations are shown on Plate 7 for the Towns area and Plate 8 for Yiyintyi area. Drilling statistics are summarised in Table 9. Drill logs and summary graphic logs are in Appendices 7 and 8 respectively.

3.4.1 RC Drilling

Drilling commenced on the 20/6/94 in the Yiyintyi area and was completed on the 5/9/94 in the northern portion of the Towns area. Most work was designed to test anomalous manganese intersections obtained from the 1993 drilling. All

drilling was carried out using a hollow hammer. This hammer was smaller than in previous years and productivity was considerably higher.

Reconnaissance drilling was completed in the Yiyintyi area as a consequence of the positive result in YER6 and occurred in the Towns area to broaden the search for manganese and better define the basement topography. Hole numbers for the Towns region are TRR94 to TRR173 for the RC drilling and TRD4 to TRD8 for the diamond drilling. Hole numbers for the Yiyintyi region are YED4, YER10 to YER26 and YER34 to YER48 for EL7263 and YER 29, YER30, YER33 and YER54 to YER60 for EL7264.

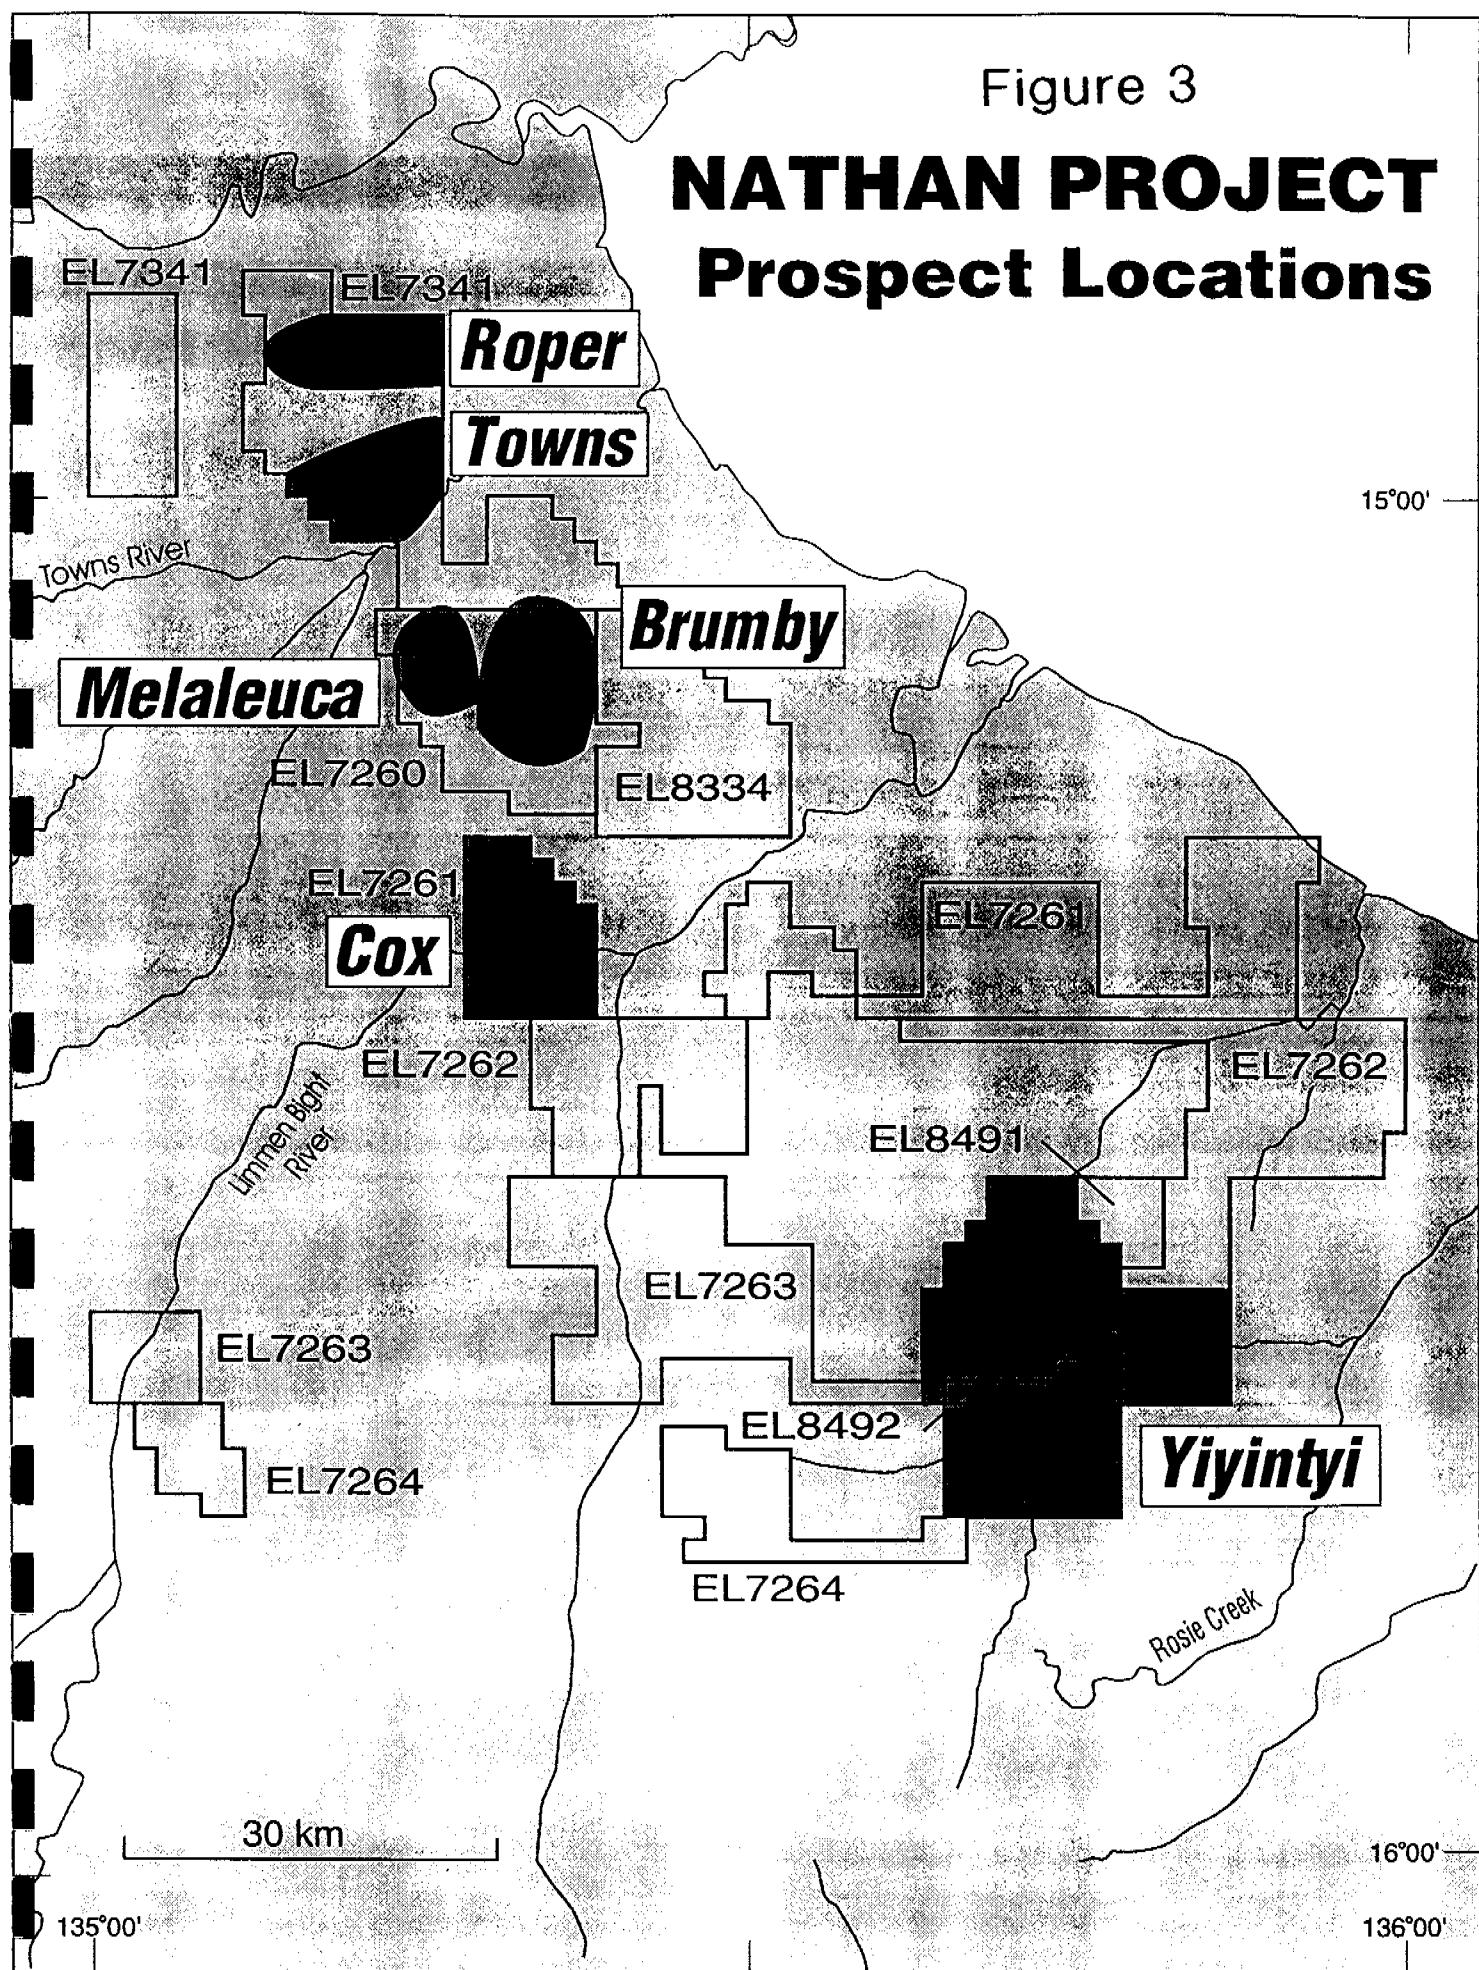

3.4.2 RC Drilling Results

The 1994 RC drilling did not meet the expectations generated from the 1993 program. Manganese mineralisation turned out to be very irregular in both its vertical and horizontal distribution. This spotty distribution must relate to primary low-grade mineralisation.

The drilling results for both the Towns and Yiyintyi areas are summarised below. The discussion is subdivided by prospects. The location of these prospects is shown in Figure 3 and a summary of results is given in Table 10. When discussing the geochemical results two types of results can occur for each sample. Samples without any suffix are 250-500 g splits of the sample interval submitted "as is" to Assaycorp, Pine Creek, NT. Samples with an 'A' suffix have been deslimed and the +0.5 mm wet sieved fraction submitted for

Figure 3

NATHAN PROJECT Prospect Locations

analysis. This process is similar to the process used for drill samples on Groote Eylandt, NT. Appendix 9 for gives the downhole analytical results for all samples collected during 1994. Table 12 gives the analytical methodology and detection limits used by Assaycorp for the analyses.

The Cox Prospect was tested by RC drill holes TRR94-101. No manganese was intersected close to TRR91 and the anomalous manganese at this locality has not been explained. However, it is clearly uneconomic. The best result was TRR100 located well north of TRR91. Manganese was intersected over 1 m and averaged 3.1% Mn. A PQ triple tube diamond hole was drilled adjacent to TRR100 and intersected a thin band of manganese within Proterozoic siltstone. Further details are given in Section 5.2.

At the Brumby Prospect four anomalous drill holes located over 8 km were intersected in 1993. The style of mineralisation was similar in all holes. During the 1994 field season RC drill holes TRR102-124, TRR133 and TRR138 tested the Brumby Prospect. The best results were:

	<u>Interval</u>	<u>Head Grade</u>	<u>Processed</u>
TRR105	42-43m	4.6% Mn	8.8% Mn
TRR108	16-16.5m	6.3% Mn	24.8% Mn
TRR120	37-38m	9.4% Mn	15% Mn

The results are very disappointing with no continuity being found and uneconomic grades intersected. Also, unlike the 1993 drilling the mineralisation occurs at a number of levels. The variation in position is interpreted as being caused by secondary remobilisation. The mineralisation will be discussed further in Section 3.4.3.

The Melaleuca Prospect was tested by RC drill holes TRR125-127 and TRR134-137. No intersections greater than a trace (up to 0.5% MnO_x) were obtained in the RC drill holes. The manganese appears to be secondary occurring on ped surfaces. Although there is no definitive evidence, the association of near surface carbonate and the manganese stained clay suggests a Tertiary age. Pliocene limestone has been recorded east of the Yiyintyi Range.

RC drill holes TRR153-156 and TRR158 tested the Towns Prospect. No intersections greater than a trace (up to 0.5% MnO_x) were obtained. The style is the same as the Melaleuca Prospect.

The Roper Prospect consists of a number of holes in the far north of the tenements. Trace manganese was identified in near surface clays during the 1993 drilling. Drilling of holes TRR167-170 tested the prospect with no intersections greater than a trace (up to 0.5% MnO_x) obtained. The area appears to have no basement topography suitable for the concentration of manganese.

A number of areas outside the existing prospects also needed testing for their manganese potential and also to elucidate the basement palaeogeography. The only positive results were obtained immediately north of the Brumby Prospect. Four wide spaced drill holes intersected mineralisation similar to most found at Brumby. The best intersections were;

	<u>Interval</u>	<u>Head Grade</u>	<u>Processed</u>
TRR114	24.5-25m	4.4% Mn	5.1% Mn
TRR128	46-46.5m	2.7% Mn	6.1% Mn
TRR130	32.5-33m	6.4% Mn	20.9% Mn
TRR131	22-24.5m	3.5% Mn	9.5% Mn

RC drill holes TRR139-152 followed-up the above four holes but did not intersect any significant manganese. Further discussion of the results can be found in Section 3.4.3.

The palaeogeography appears to be important in localising the Groote Eylandt manganese. An indication of the Cretaceous palaeogeography in the Towns area is shown in Plate 7 where the RL of the top of the Proterozoic has been contoured. For the most part drill hole data has been used, but RLs of outcropping Proterozoic were included in the points contoured for the southern part of the area. Holes which lack a confidently interpreted Proterozoic intersection were not used.

Plate 7 agrees reasonably well with current published geological mapping and shows that a pronounced embayment in the Proterozoic surface occurs in the centre of the Towns area. The holes comprising the Brumby Prospect, which have the highest manganese assays, are located close to the southern shore of the embayment. This presumably reflects the palaeogeographic location that allowed deposition of manganese oxides at that time in the Cretaceous. Although most of the manganese intersections appear secondary the mineralisation is probably reflecting primary syn-depositional manganese.

The main focus of drilling at the Yiyintyi was to follow up YER6 from 1993. YER6 had returned an assay of 17.9% Mn headgrade and 39.1% Mn washed grade over the interval 20 to 22 metres. This result was considered very significant because it is close to ore grade and it was thought that the mineralisation could have been primary.

Extensive RC drilling around YER6 failed to locate any significant extensions of this mineralisation. Only hole YER36, located approximately 100 m WSW of YER6 intersected mineralisation. YER36 intersected 1.0 m at 10.2% Mn headgrade and 24.9% Mn washed grade. Further discussion on the mineralisation will be given in Section 3.4.3.

Additional reconnaissance drilling within the Yiyintyi area, E7263 and E7264, failed to intersect any anomalous manganese.

3.4.3 Diamond Drilling

The aim of the diamond drilling was to allow a better understanding of the mineralisation intersected from the RC drilling. PQ triple tube was employed to maximise core recovery. Drilling problems near the mineralisation still occurred.

Table 11 summarises the diamond drilling completed for manganese.

The intersection in TRR79 (drilled in 1993) was followed up by TRD3 (Plate 9) which revealed the mineralisation to occur as manganese oxide replacements making up about 10% of a silicified oolite. Smaller zones of manganese, ranging from 1 to 5% manganese oxide, occurred over intervals of up to 10 to 20 cm. Core recovery near the indicated manganese horizons was poor probably indicating major dissolution. This is confirmed by the cavernous nature of the underlying silicified dolomite. Although some manganese may be at the primary deposition site all the mineralisation is secondary. The patchy distribution is probably reflecting more the low primary grade of the manganese rather than the secondary mobilisation.

The intersection in TRR108 was followed up by diamond hole TRD4 (Plate 10). The main intersection occurs at 23.8 to 24.2 m where approximately 25% MnO_x forms the matrix to a quartz sand. Minor evidence from the diamond drilling and adjacent RC drilling indicated that this style has no lateral continuity. This mineralisation has no economic significance but is interesting

in that it appears to have deposited higher in the sequence. In most instances manganese tends to migrate downwards and there is no obvious evidence for an aquaclude to reverse the fluid direction.

Hole TRD5 (Plate 11) tested TRR100 at the Cox Prospect. TRD5 intersected Proterozoic laminated pink and green siltstone with common brecciation and carbonate veining from 11.4 to 13.5 m. A stratabound 3 cm massive band of manganese occurs at 14.1 m. From 14.5 m trace manganese occurs as blocky to oblate Mn oxide replacement aligned along laminations in the siltstone host rock. The origin of the manganese is uncertain but may well be Proterozoic.

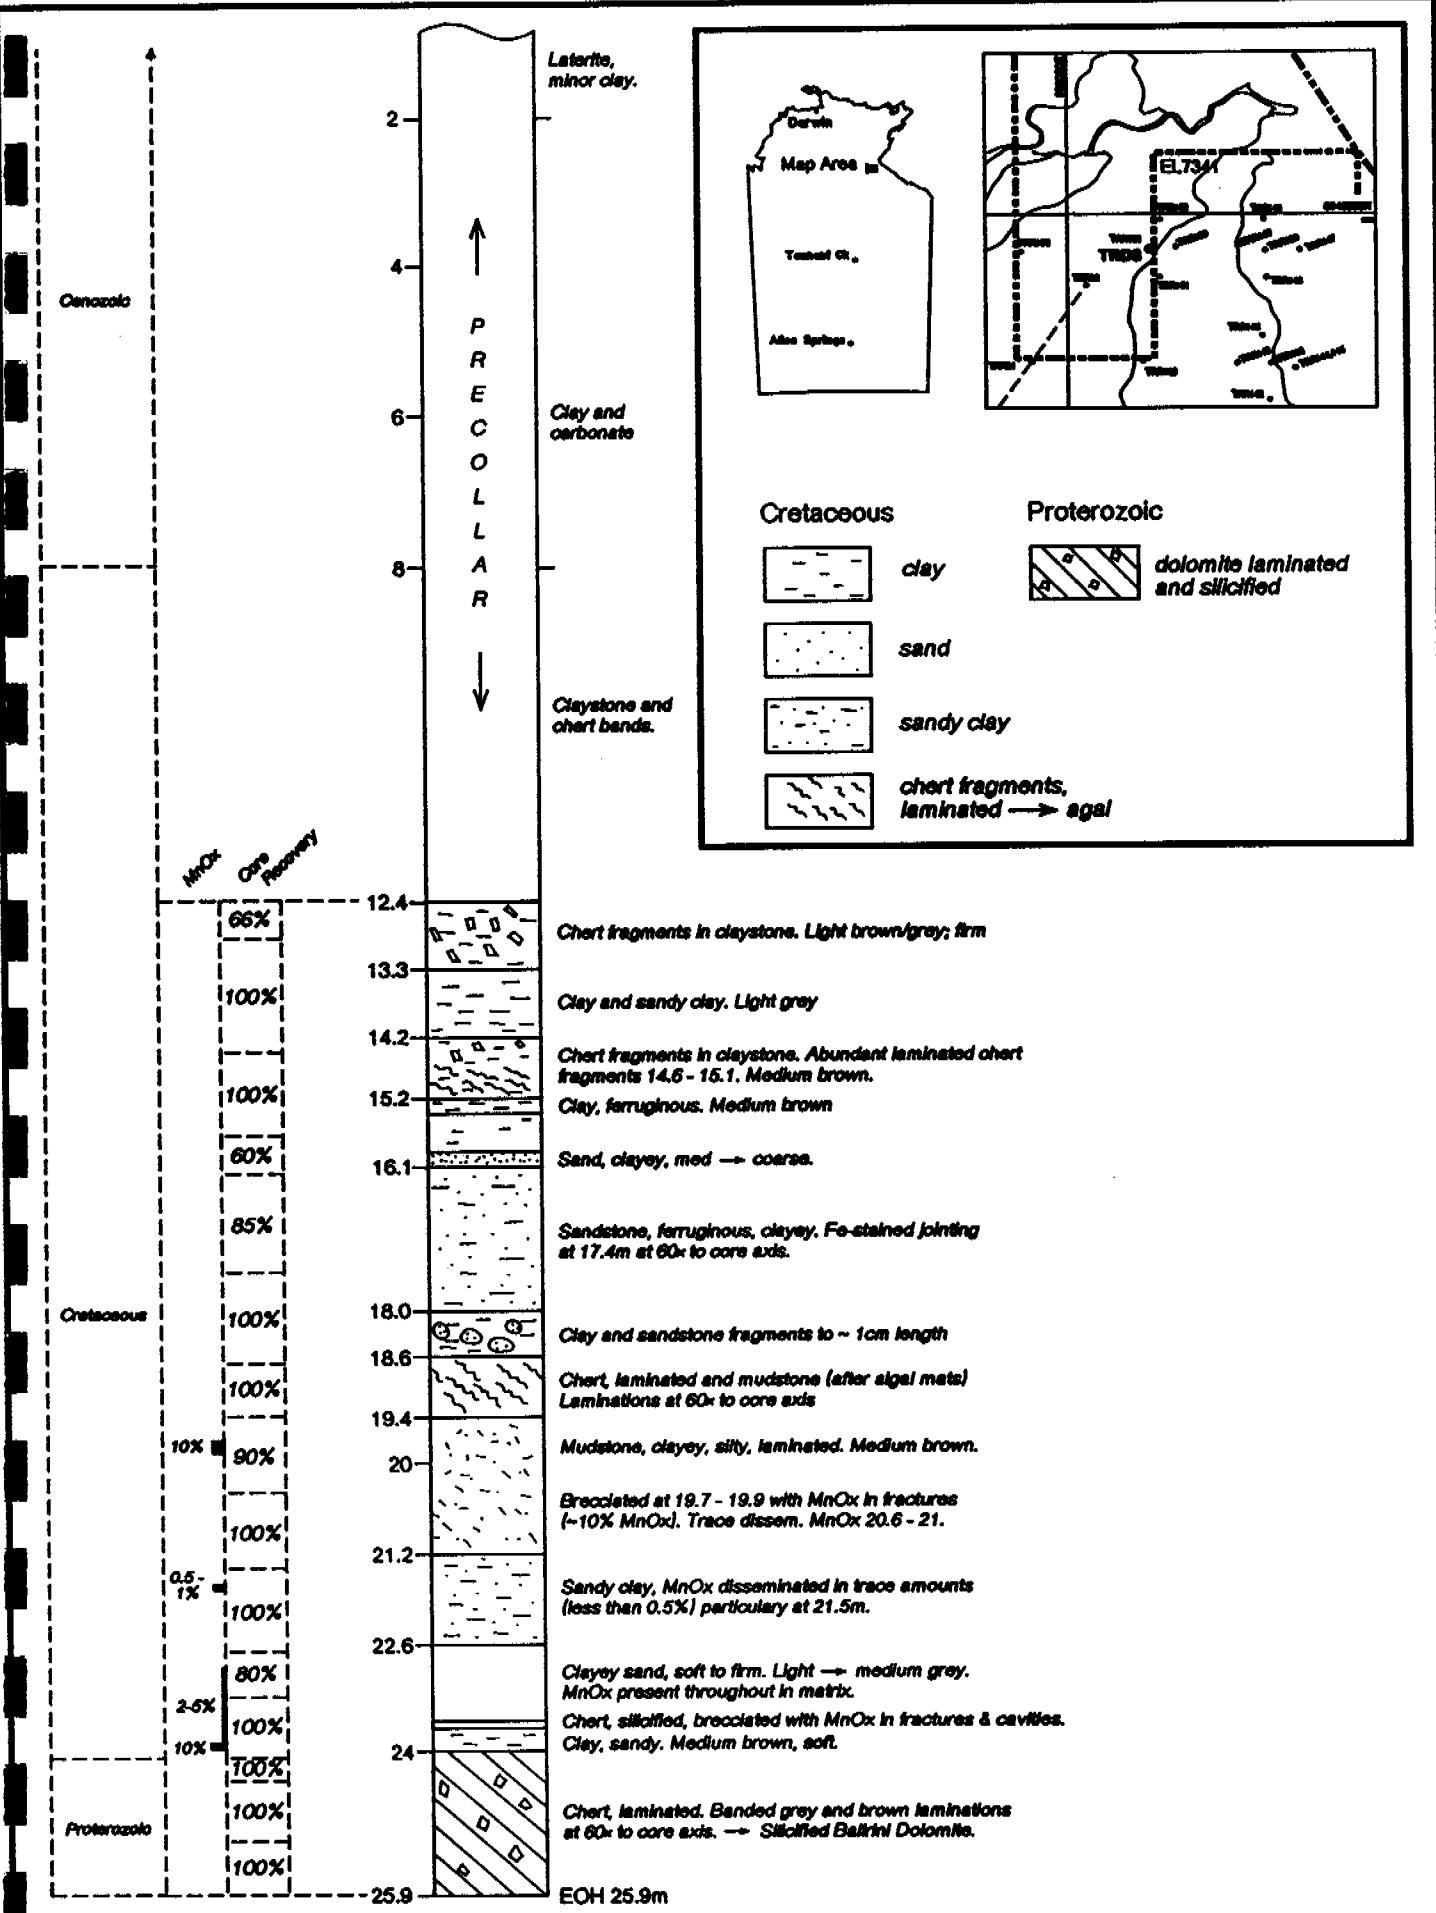

TRR67 was the best and shallowest intersection located in the Brumby Prospect during 1993. This was followed-up by TRD6 and TRD6A (Plate 12). TRD6 was abandoned at 18 m in running sands, however TRD6A confirmed the intersection obtained in TRR67. From 32.25 to 32.5 m there occurred 90% manganese oxide replacement of a silicified aggl siltstone. The manganese although secondary may be replacing primary manganese. Lower grade intersections (1 to 10%) occurred intermittently throughout TRD6A including botryoidal manganese below the interpreted Cretaceous-Proterozoic boundary.

TRD7 (Plate 13) was collared adjacent to TRR15 and intersected clay and sandy clay averaging 10% manganese oxide from 8.1 to 8.3 m. The clay/sandy clay has a distinct very pale green colour and is interpreted as a Pliocene near shore deposit. Weathering has caused the manganese to form an irregular

mottling along ped boundaries. The manganese is clearly secondary but its origin is unknown.

Diamond hole TRD8 (Figure 4) was drilled three metres from TRR131 and intersected minor MnOx (up to 10%) from 22.6 to 23.7 m. The MnOx occurs in the matrix of a clayey sand from 22.6-23.6 m and for the last ten centimetres occurs as coatings on fractures and cavities of a siliceous chert. The mineralisation is probably secondary.

Diamond hole YED3 was drilled adjacent to YER6 (the two collars were about 2 metres apart) and intersected manganese mineralisation, estimated at +20% Mn from 20.2 to 21.2 m. An attempt to use our computer logging system was made on YED3. It was found to be unsatisfactory and traditional methods were used for the remaining holes. The computer generated log is located in Appendix 7. The manganese appears to be secondary but occupies a primary depositional site. The reasonable thickness but low-grade appears related to the small manganese source area. To the west of the intercept (and YER36) a basement ridge effectively isolates the area from anoxic zones to the west. The only source is a small anoxic zone a few hundred metres to the south east (YER22). The conditions were favourable for manganese deposition but the system was too small to produce an economic resource.

3.4.4 Sampling and Assay Results

Drill samples were processed in the field and analysed at Assaycorp Pty Ltd, Pine Creek, NT. The suite of elements and specifications are given in Table 12 while the results are located in Appendix 9. Significant results are summarised below.

The field sample treatment consisted of first drying the sample and splitting off approximately 250-500 g which was analysed without further processing. This analysis is referred to as the headgrade assay. The remainder of the sample was deslimed and then sieved at 0.5 mm. The minus 0.5 mm fraction was discarded and the plus 0.5 mm fraction was weighed and analysed. This second analysis is referred to as the processed assay. Sample numbers have the suffix "A" to denote processed assays. The purpose of the sample treatment was to provide a better indication of potential product grade than that provided by the headgrade assays.

The assay results generally confirm the estimated manganese intersections, although the ranking of holes changes when considering the processed analysis. In general the processed analysis will give a higher result than the headgrade analysis; a function of discarding fine clays and silica.

The Brumby Prospect offered the best potential at the start of the season. This was not confirmed by the 1994 drilling. However, the best analyses are summarised in Table 13.

Hole TRR108 has the best processed grade at 24.8% Mn. Other holes also have grade of similar magnitude; TRR100 and TRR120. In all of these holes there is an upgrading of 3 to 4 times. The grade of these intercepts is clearly uneconomic and the degree of upgrading would indicate that yields would not be satisfactory even if the grade was higher.

The only other holes from the Towns region to produce significant assays were TRR130 and TRR131. Both of these holes were sited as general reconnaissance holes north of the Brumby Prospect. A summary of the best results is given in Table 14.

For these holes processed grades up to 20.9% Mn and 12.6% Mn were obtained. As noted previously, follow up drilling around TRR130 and TRR131 failed to locate any further mineralisation.

In summary, all the analytical results from the Towns area indicate that no potentially economic intersections of manganese were obtained.

At Yiyintyi the only intersection of any significance within the areas covered by this report was YER36 (Table 15). This hole was located about 100 m WSW of YED3 and YER6 and has 1.5 m averaging 7.8% Mn head grade and 21.8% Mn processed grade.

3.4.5 Downhole Geophysics

An EM39 borehole induction tool (Geonics) was used to log 21 holes in the Yiyintyi and Towns regions. This logging was completed in an attempt to explain near surface conductors that could not be easily explained from the drill chips. The drill holes logged included eight which intersected manganese.

The conductivity readings were taken at 10 cm intervals down the hole and the recorded data dumped onto a laptop computer. It should be noted that when a layer is less than 4 m thick the EM39 does not accurately log the conductivity due to averaging of adjoining beds. The recorded conductivity is 50% of actual at 0.5 m, 75% of actual for 1 m and 90% of actual for 2 m.

The profiles with downhole geology are located in Appendix 10.

The EM39 picks out lithological boundaries quite well. The highest responses are yellow/pale green clays and manganese. From this work it is concluded that the airborne EM anomalies are being caused by discrete zones of conductive clay. There is no evidence to suggest that any of the manganese is the sole cause of any of the airborne EM anomalies tested.

4.0 EXPLORATION EXPENDITURE

Exploration expenditure for the period 24th May, 1994 to 23rd May, 1995 amounted to \$ 799,982. A detailed breakdown of expenditures is given in Appendix 11.

5.0 CONCLUSIONS AND RECOMMENDATIONS

5.1 Diamond Exploration

Encouraging results for EL 7263 and EL 7264 on the Mantungula 1:100,000 sheet demonstrates not only the prospectivity of the region but also the difficulty in discovering and defining indicator anomalies.

Continued follow-up and reconnaissance exploration is thus warranted.

5.2 Base Metal Exploration

Ground TEM follow-up of nine QUESTEM anomalies in 1994 identified three bedrock conductors worthy of drill testing in addition to a further two conductors worthy of drill testing identified by ground TEM in 1993.

Reinterpretation of a QUESTEM airborne TEM survey flown by BHP in 1992 has resulted in the selection of a further eleven lower conductance anomalies for ground detailing in 1995. Soil sampling follow-up of four QUESTEM anomalies hosted by Roper Group sediments failed to identify any anomalous base metal geochemistry.

A 22 site TEM sounding program on E7262 has identified a significant bedrock conductor at one site. A further seven TEM soundings will be undertaken in 1995 to test the western extent of this conductive layer, possibly followed by drill testing.

Drill testing of five bedrock conductors failed to identify any anomalous base metal geochemistry. In each case, the bedrock conductor was explained by the presence of dark, variably carbonaceous and micaceous, laminated mudstones, all interpreted to be Proterozoic.

The extensive manganese exploration program carried out in the Nathan Project Tenements over the past few years has comprehensively tested the Cretaceous sediments. Although manganese has been intersected, the size and grade are not of economic significance.

Additional manganese exploration is not warranted on this area.

6.0 PROPOSED PROGRAMME AND BUDGET

The proposed programme and budget for the period 24th May, 1995 to 23rd May, 1996 is given below. Under the McArthur River Joint Venture, BHP Minerals have elected to withdraw from exploration licences 7260 and 7341. No further work will be carried out by BHP on these licences.

EL 7260

DIAMOND EXPLORATION:

1. Reconnaissance sampling.
2. Follow-up sampling if warranted.
3. Helimag survey if warranted.

PROPOSED EXPENDITURE:

Labour	7,000
Field Support	5,000
Vehicles	2,000
Helicopter Charter	8,000
Geophysics	12,000
Laboratory	5,000
Drafting/Computing	1,000
	<hr/>
	\$ 40,000

EL 7261

DIAMOND EXPLORATION:

1. Reconnaissance sampling.
2. Follow-up sampling if warranted.
3. Helimag survey if warranted.

BASE METAL EXPLORATION:

1. Ground TEM follow-up of one QUESTEM anomaly.
2. Drill testing one QUESTEM anomaly.
3. GEOTEM survey over a magnetic anomaly.

PROPOSED EXPENDITURE:

Labour	7,000
Field Support	5,000
Vehicles	2,000
Helicopter Charter	8,000
Geophysics	12,000
Laboratory	5,000
Drafting/Computing	1,000

TABLE 11
SUMMARY OF DIAMOND DRILLING

DIAMOND HOLE	ADJACENT RC HOLE	RESULT
TRD3	TRR79 (1993)	secondary MnOx occurs irregularly from 36-45m. Best MnOx occurs at base poss. related to downward moving ground water. MnOx almost certainly related to Cretaceous not Pro.
TRD4	TRR108	secondary MnOx occurs irregularly from xxxxxx highest grade occurs as matrix to sand. This mineralisation is very irregular.
TRD5	TRR100	thin band (3cm) of MnOx plus other traces intersected within Pro. siltstone
TRD6	TRR67 (1993)	abandoned in running sands
TRD6A	TRR67 (1993)	confirmed intersection in TRR67, no definite primary ore located. Strong indication that manganese is Cretaceous.
TRD7	TRR15 (1993)	10% MnOx occurs from 8.1-8.3 as irregular mottling, occurs on ped boundaries
TRD8	TRR131	minor MnOx (to 10%) from 22.6-23.7
YED3	YER6 (1993)	secondary manganese, including thin massive bands occur over 1.1m. Although secondary appears to be a primary deposition site. Occurrence has very limited extent.

APPENDIX 4.

Soil and Rock Sampling Analytical Results

SOIL SAMPLE ANALYSIS DESCRIPTION

Scheme Code: GP031

Sample preparation of soil samples; dry, fine pulverise

Scheme Code: D140

Aqua regia/perchloric acid digest (0.3g sample)

Scheme Code: GA140

AAS determination

Cu: Copper

Pb: Lead

Zn: Zinc

Fe: Iron

Mn: Manganese

CARPENTARIA REPUBLICAN FAFIDW

DDH MYD002 LOG

0-14m	Green, brown and red, highly weathered, laminated mudstone. Significant clay.
14-30m	Medium brown, green and red, weathered, laminated mudstone. Minor clay.
30-36m	Medium brown, massive to laminated, fine mudstone. Minor green interbeds. Minor coarse silt sized interbeds. Base of oxidation.
36-58m	Dark green, medium red-brown and minor black, laminated mudstone. Minor green interbeds.
58-60m	Medium grey-green, dololutite. Very minor thin quartz arenite interbeds.
60-62m	Banded dark and light green, laminated, dolomitic mudstone.
62-66m	Dark grey, laminated mudstone. Trace very fine pyrite 62-64 m.
66-78m	Dark brown, bedded dolomitic mudstone. Minor green interbeds.
78-90m	Dark grey, laminated mudstone. Minor pyrite including bedded pyrite at 84-86 m. Minor quartz veining. Some bedding planes are carbonaceous.
90-120m	Dark grey to black, laminated, variably carbonaceous mudstone. Fine mica on some bedding planes? End of RC pre-collar.
120.3-146.8m	Dark green to green-grey, laminated, weakly carbonaceous mudstone. Carbonaceous material occurs as small flecks on bedding planes and in thin beds that commonly grade up into flecked mudstone. Minor carbonate veining. Minor chalcopyrite in carbonate vein at 123 m. Several small fault zones. Minor polished and striated carbonaceous slip surfaces.
146.8-148.3m	Shear zone. Four main intervals of crushed mudstone/clayey gauge within a fractured dark grey green, laminated carbonaceous mudstone. Numerous polished and striated carbonaceous slip surfaces.
148.3-155.8m	Dark green-grey, laminated, variably carbonaceous mudstone. Thin beds of highly carbonaceous mudstone commonly grading up in to carbonaceous flecked mudstone. Minor soft sediment deformation. Blebs of pyrite on fractures. Minor fine disseminated pyrite at 155.8 m.

155.8-157.3m	Dark green-grey, laminated, variably carbonaceous mudstone. Minor black carbonaceous mudstone interbeds. Extensive disruption of bedding due to soft sediment deformation.
157.3-163.7m	Darkest grey-black to black, laminated, carbonaceous mudstone. Extensive disruption of bedding due to soft sediment deformation. Carbonate veining. Blebs of pyrite on fractures.
163.7-165.4m	Medium-light green, laminated, weakly carbonaceous (finely micaceous?) mudstone. Minor black carbonaceous mudstone interbeds. Bedding commonly disrupted. Trace bedded pyrite at 164.6 m.
165.4-180.0m	Darkest green to black, laminated carbonaceous mudstone. Minor medium green mudstone interbeds. Orange-brown siderite? spots after evaporites? in several places. Blebs of pyrite on fractures. 20% disseminated pyrite bed at 175.5 m.
180.0-182.3m	Darkest green to black, micaceous carbonaceous mudstone with minor interbedded light pink coloured well sorted quartz sandstones. Soft sediment deformation common.
182.3-183.7m	Medium green, interbedded mudstone, fine sand/coarse siltstone and black carbonaceous micaceous mudstone. Becomes dolomitic at base of interval. Minor pyrite and chalcopyrite in fractures and smeared on bedding planes.
183.7-186.8m	Medium red-brown, dolomitic mudstone. Minor pyrite in veins. Some coarse silt sized interbeds.

E.O.H.

0-186.8m Proterozoic Mantungula Formation?

DDH MYD003 LOG

0-12m	Medium brown to red-brown, clay, unconsolidated sand, rounded quartz arenite pebbles, siliceous algal dolomite and dark grey siltstone fragments. Transported cover.
12-22m	Medium green to red and dark red-brown, laminated, mudstones. Highly weathered clay horizons. Chlorite? on fractures.
22-36m	Medium red-brown, laminated mudstone. Minor interbedded, fine sand sized ferruginous quartz arenite. Very minor green mudstone interbeds. Base of oxidation?
36-44m	Medium red-brown, mudstone. Interbeds of medium-dark green mudstone.
44-46m	Medium-light green, bedded, fine sand sized, quartz arenite. Lesser interbedded, red-brown, mudstone.
46-48m	Darkest grey to black, laminated, carbonaceous mudstone. Minor light green-yellow coarse silty beds.
48-62m	Medium-dark to light green, laminated mudstone. Very minor black carbonaceous mudstone interbeds.
62-78m	Medium to dark red-brown, laminated mudstone. Minor thin light green mudstone interbeds.
78-102m	Dark green-grey, laminated, weakly micaceous mudstone. Small flecks of mica visible on bedding planes.
102-120m	Dark green-grey, laminated, weakly carbonaceous mudstone. Bedded and disseminated flecks of carbonaceous material. End of RC pre-collar.
120.3-120.4m	Medium red, well sorted, fine sand sized, silicified quartz arenite. Some orange mottling.
120.4-132.0m	Dark to darkest green-grey, massive to laminated, weakly carbonaceous mudstone. Carbonaceous flecks on bedding planes.
132.0-143.5m	Dark to darkest green, massive to laminated, variably carbonaceous and micaceous mudstone. Increasingly micaceous and carbonaceous towards base of interval. Minor faulting.
143.5-143.7m	White, sandy mudstone. Evaporite replacement by silica?
143.7-151.4m	Dark green, laminated, carbonaceous, micaceous mudstone. Minor faulting. Trace chalcopyrite at 150.7 m. Minor quartz arenite beds.

151.4-151.5m	Medium green, bedded very glauconitic quartz arenite. Interbedded with green to black laminated carbonaceous, micaceous mudstone.
151.5-154.4m	Dark green to black, laminated, carbonaceous, micaceous mudstone.
154.4-154.9m	Medium green, laminated mudstone. Small grains and laths of siderite? after evaporites? Trace fine disseminated pyrite and chalcopyrite.
154.9-156.1m	Darkest green to black, laminated carbonaceous, micaceous mudstone.
156.1-156.6m	Medium green, laminated, mudstone. Very fine sand sized grains of siderite? in mud matrix.
156.6-157.3m	Darkest green to black, laminated carbonaceous, micaceous mudstone.
157.3-158.5m	Medium green, bedded mudstone. Fault at base of interval.
158.5-161.0m	Darkest green to black, laminated carbonaceous, micaceous mudstone. Mottled medium green and red zone 159-159.5 m.
161.0-163.3m	Black to red-brown to green, variably carbonaceous, micaceous mudstone. Convolute bedding in places.
163.3-166.7m	Medium green-brown to dark red (gradual change in colour), laminated, micaceous mudstone. Very minor thin grey, very fine sand sized, arenite beds towards base of interval.
166.7-171.4m	Dark red-brown, massive, micaceous mudstone. Minor faulting. Minor yellow (limonite?) and green (chlorite?) staining on fractures.

E.O.H.

0-12m	Recent cover
12-171.4m	Proterozoic Mantungula Formation.

WHOLE ROCK ANALYSIS DESCRIPTION

Scheme Code: GP032

Sample preparation of percussion/rock/core samples; dry, jaw crush, fine pulverise

Scheme Code: D140

Aqua regia/perchloric acid digest (0.3g sample)

Scheme Code: GI140

ICPOES determination

Cu: Copper

Pb: Lead

Zn: Zinc

Fe: Iron

Mn: Manganese

As: Arsenic

Ni: Nickel

Co: Cobalt

Mo: Molybdenum

Cr: Chromium

P : Phosphorus

V : Vanadium

Cd: Cadmium

Ag: Silver

Scheme Code: OX408

Glass fusion XRF (preferred method for silicates)

Fe₂O₃: Iron Oxide

MnO: Manganese Oxide

K₂O: Potassium Oxide

MgO: Magnesium Oxide

Na₂O: Sodium Oxide

Al₂O₃: Alumina

SiO₂: Silica

TiO₂: Titanium Dioxide

CaO: Calcium Oxide

P₂O₅: Phosphorus Pentoxide

Scheme Code: OM615

Loss on Ignition (LOI) - gravimetric

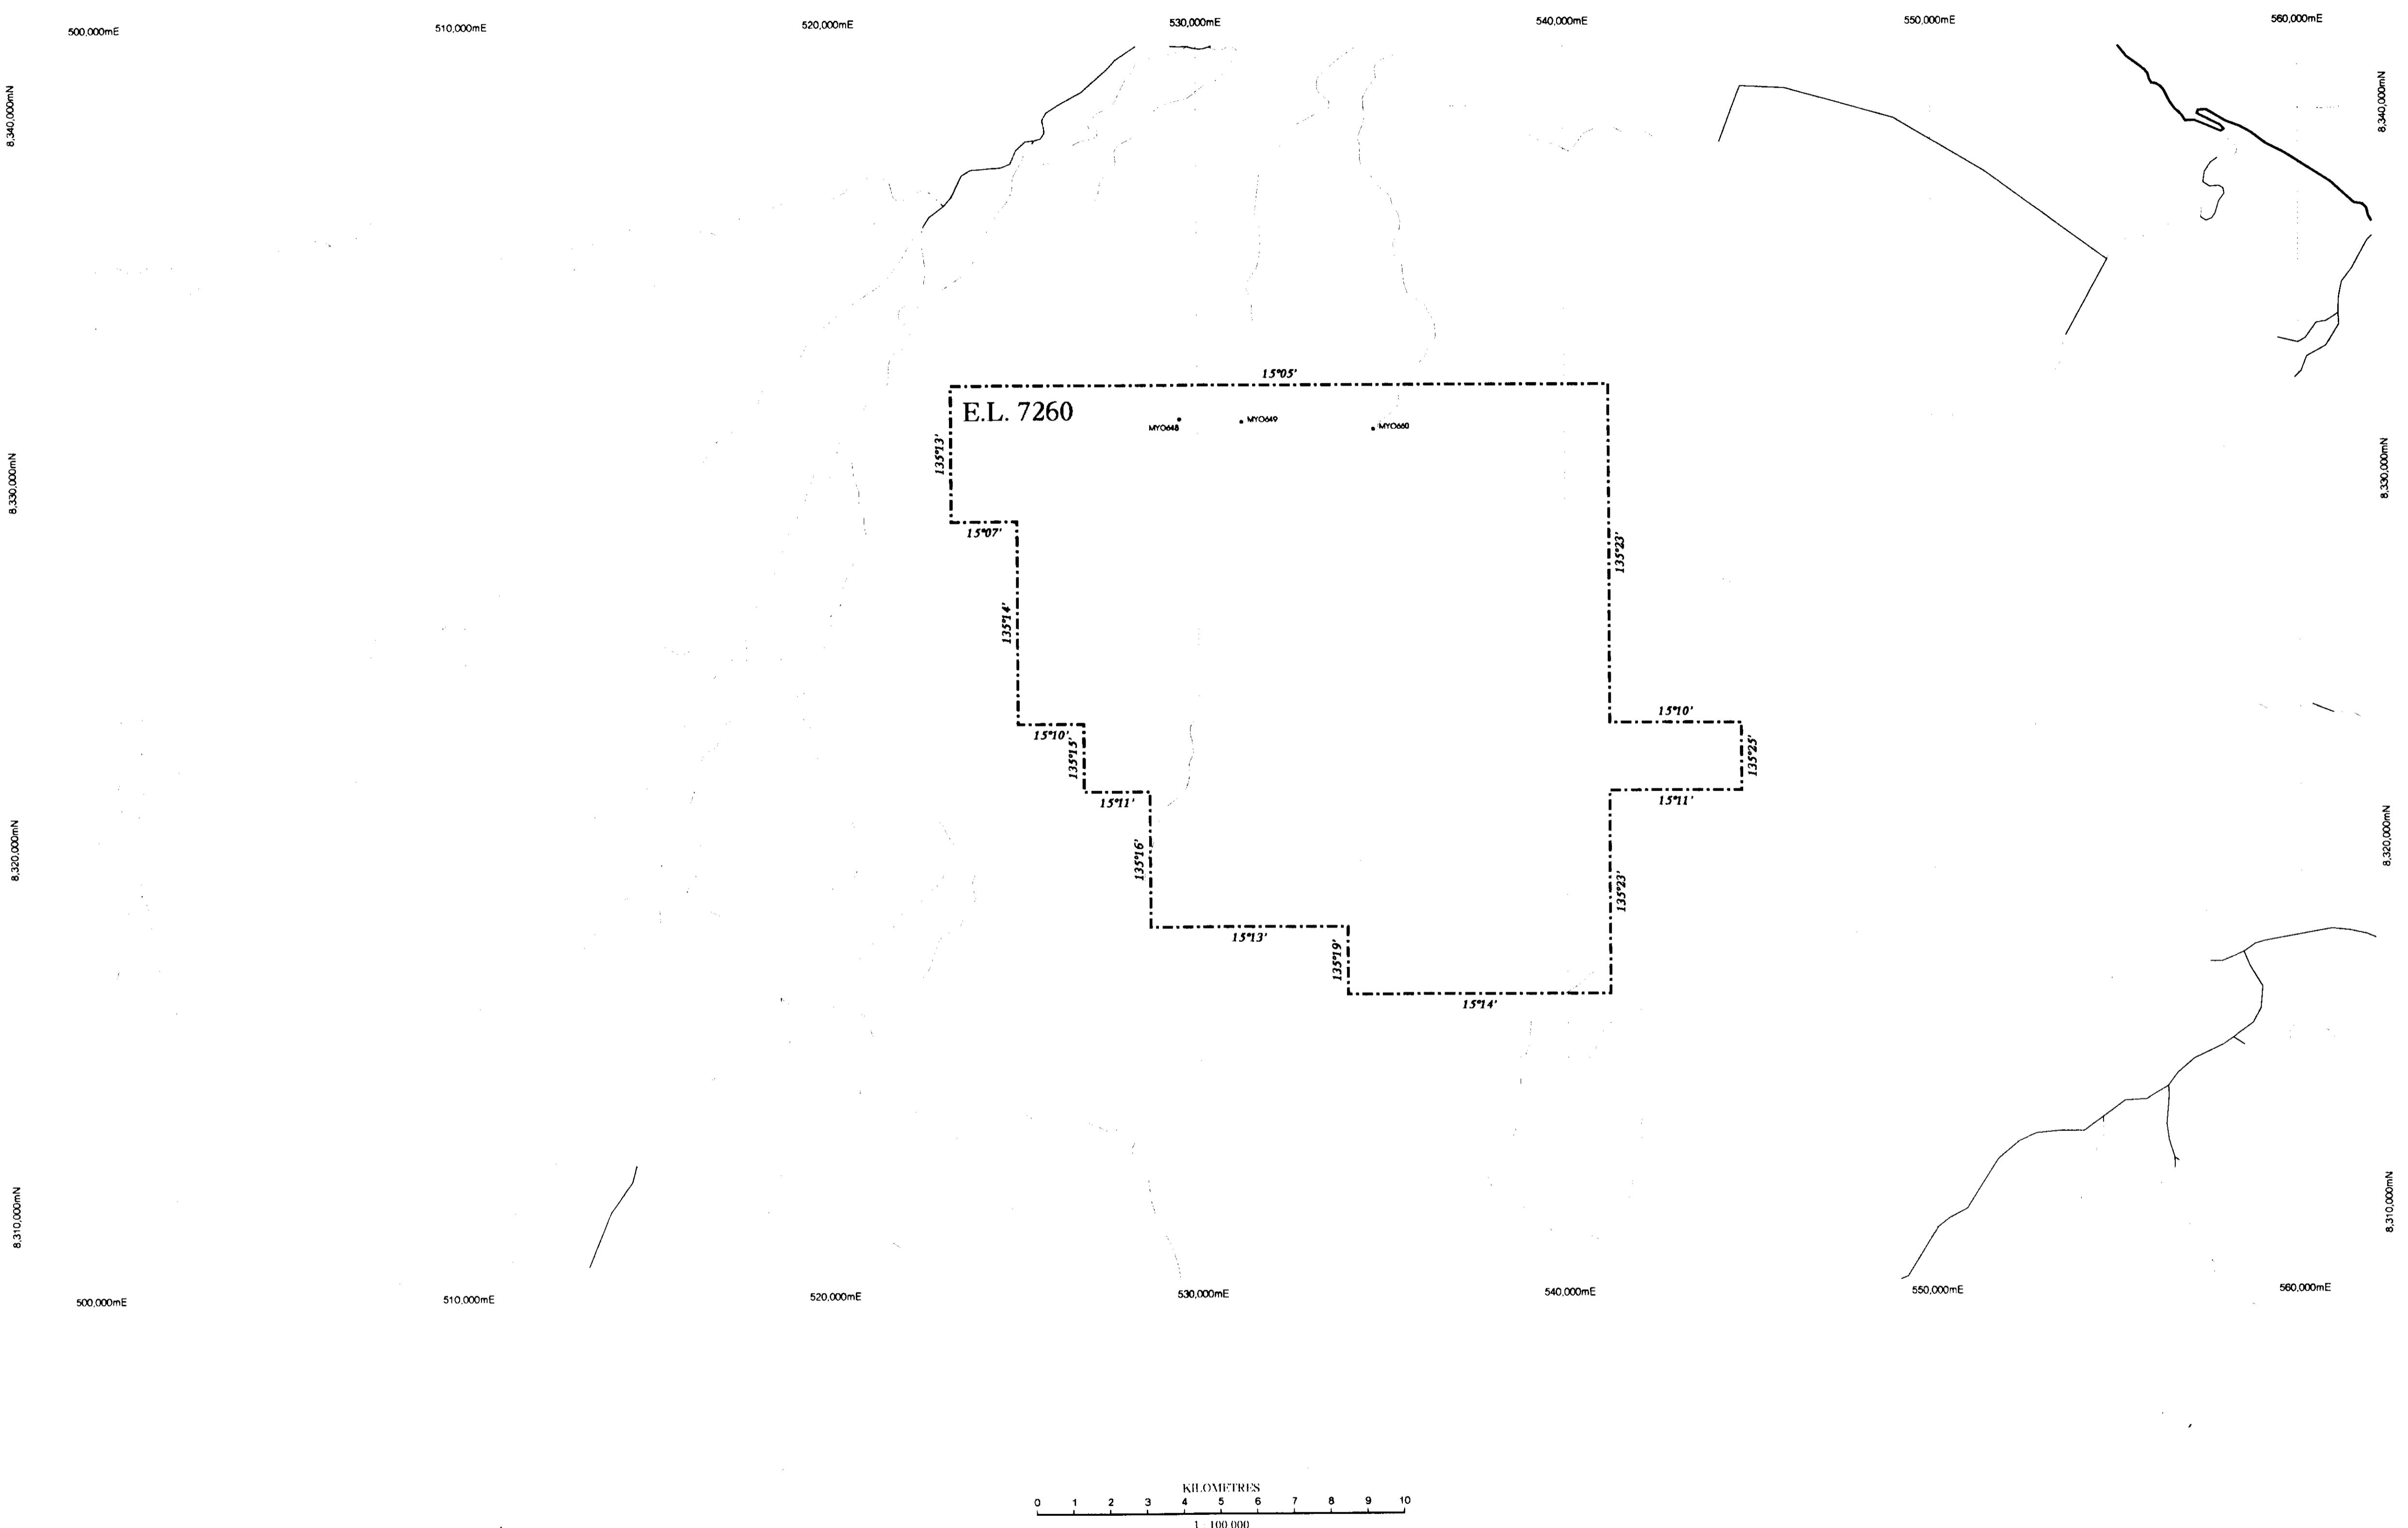

LOI: Loss on Ignition

## LEGEND FOR GRAPHIC DRILL LOGS

### Rock Types

-  Laterite, soil, surficial sand
-  Clay, claystone, silt, mudstone
-  Sand
-  Sandstone
-  Manganese ore
-  Mixed clay and chert
-  Conglomerate
-  Chert
-  Limestone, carbonate (general)
-  Shale, siltstone
-  Dolomite

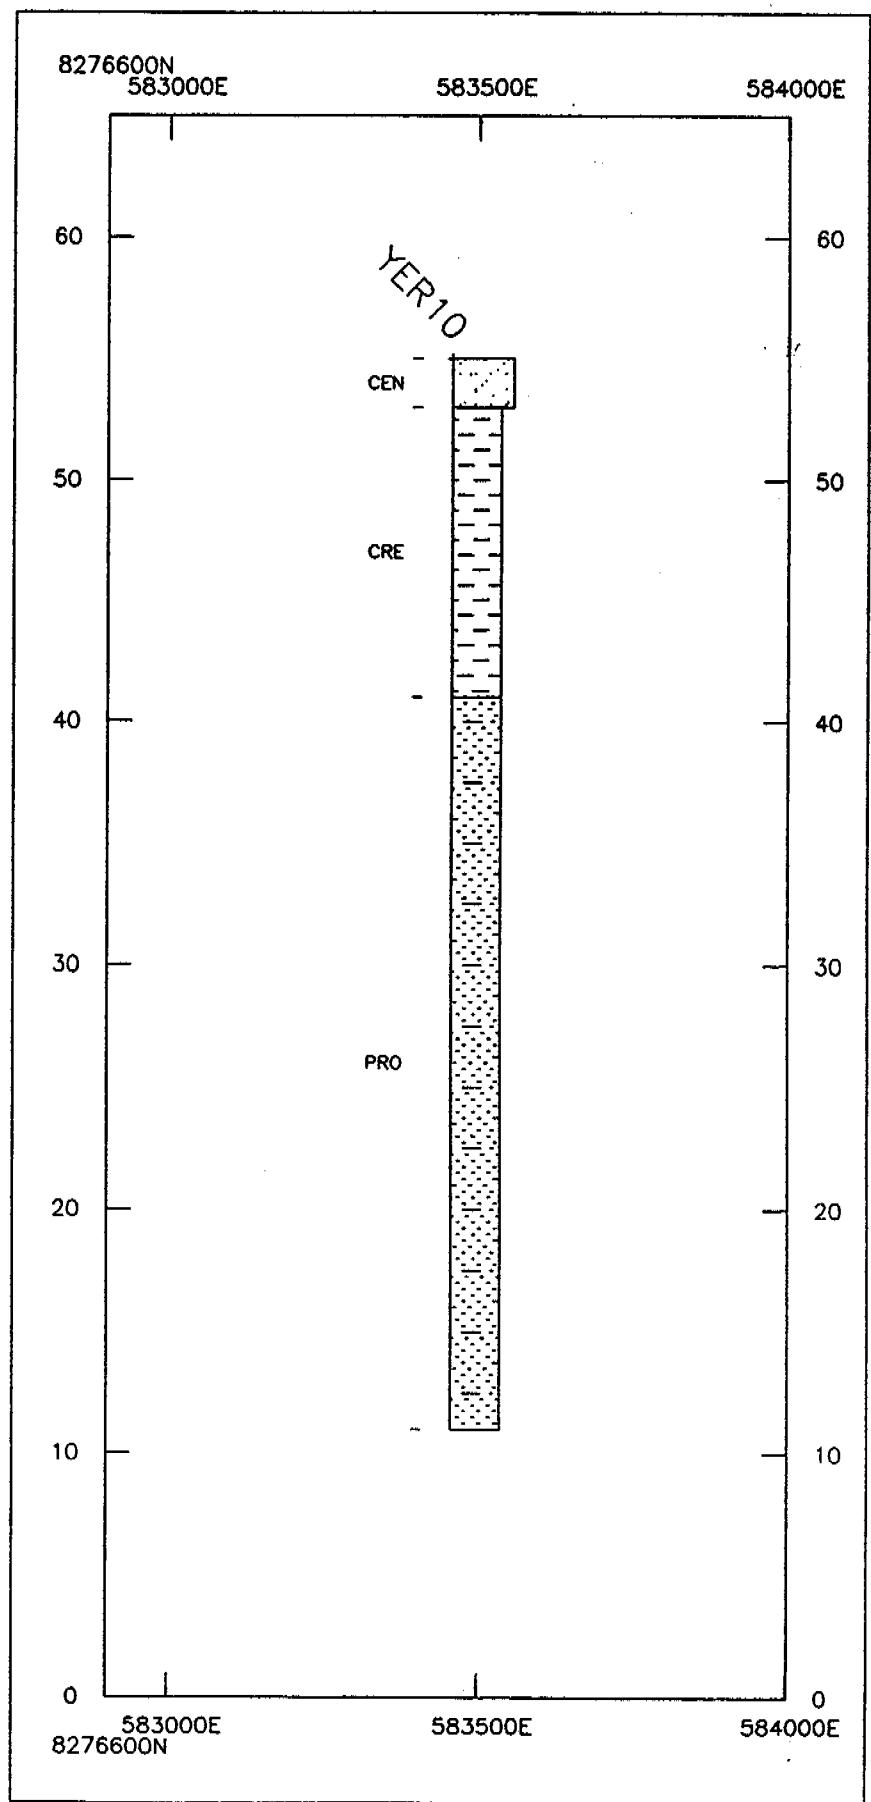

### Stratigraphy

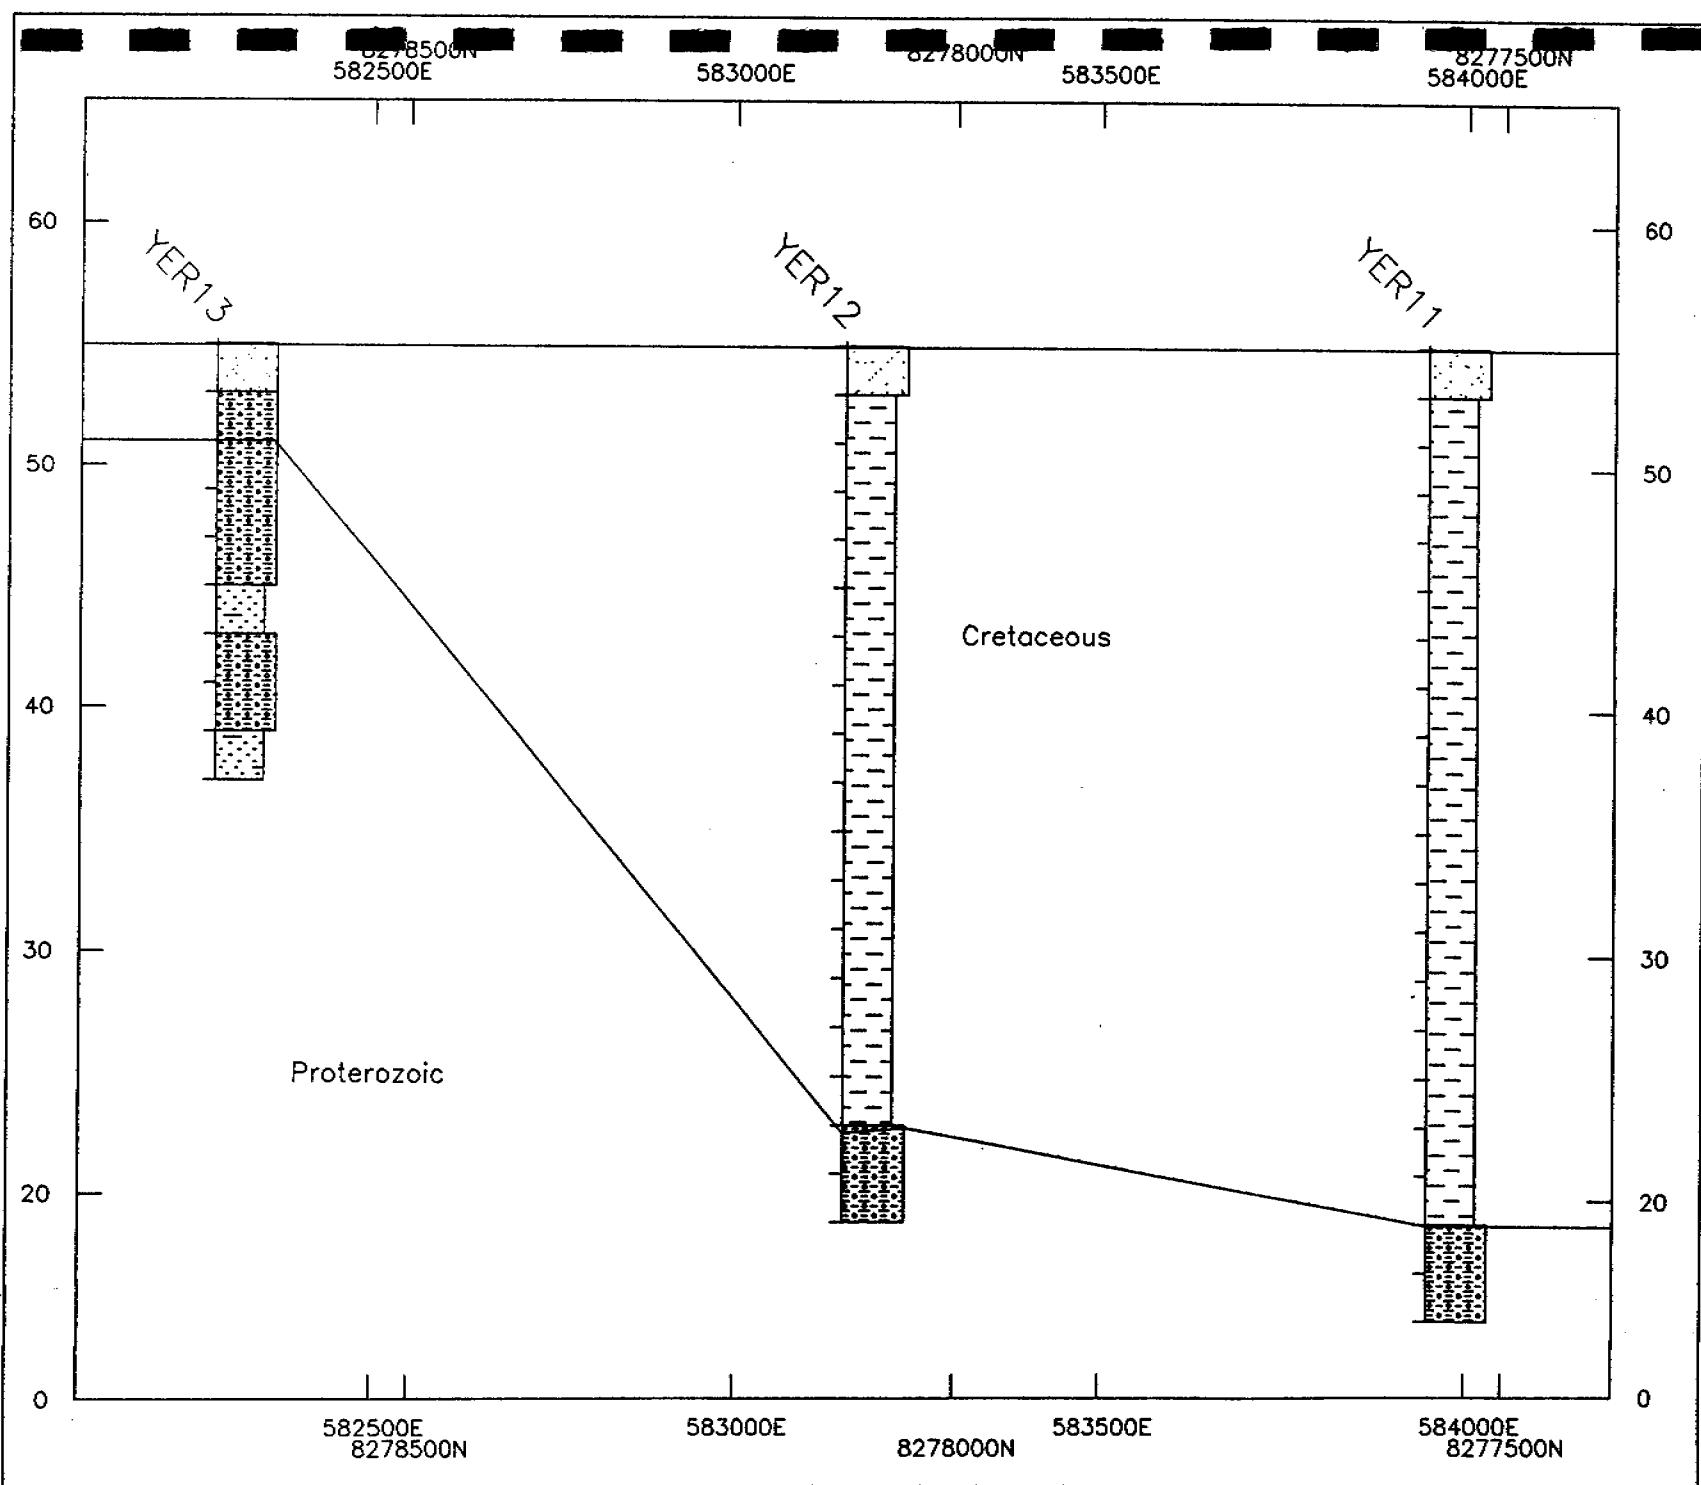

- CEN – undifferentiated Cenozoic
- CRE – Cretaceous
- PRO – undifferentiated Proterozoic
- OTH – unknown

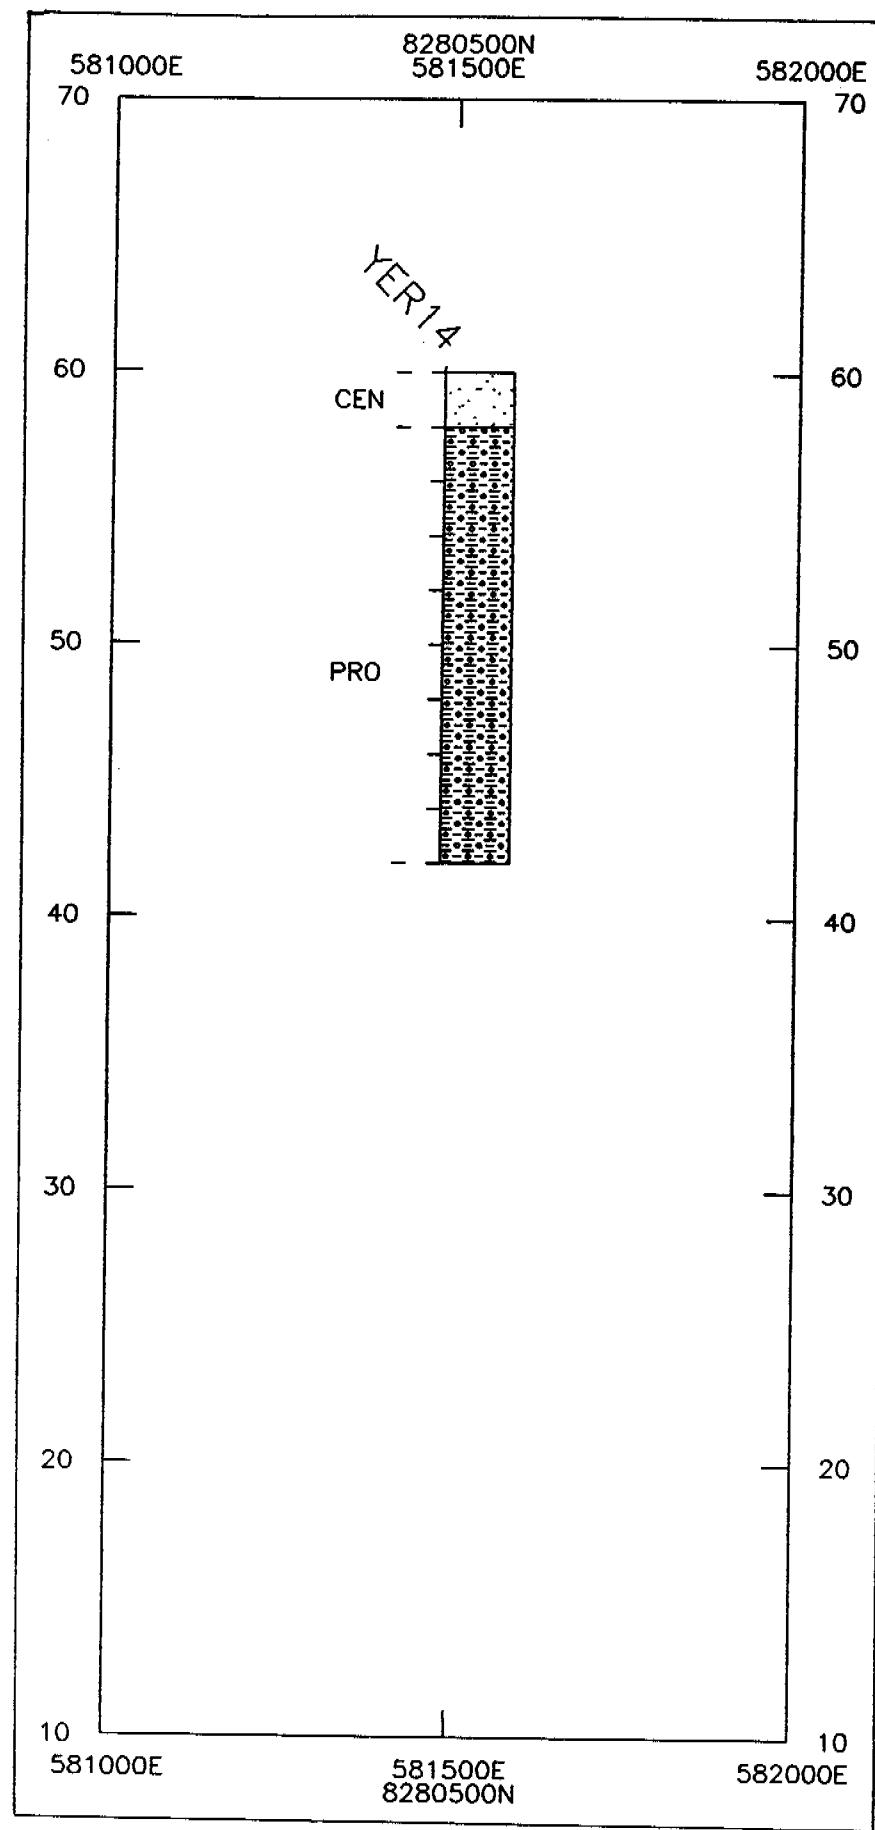

### Mineralisation

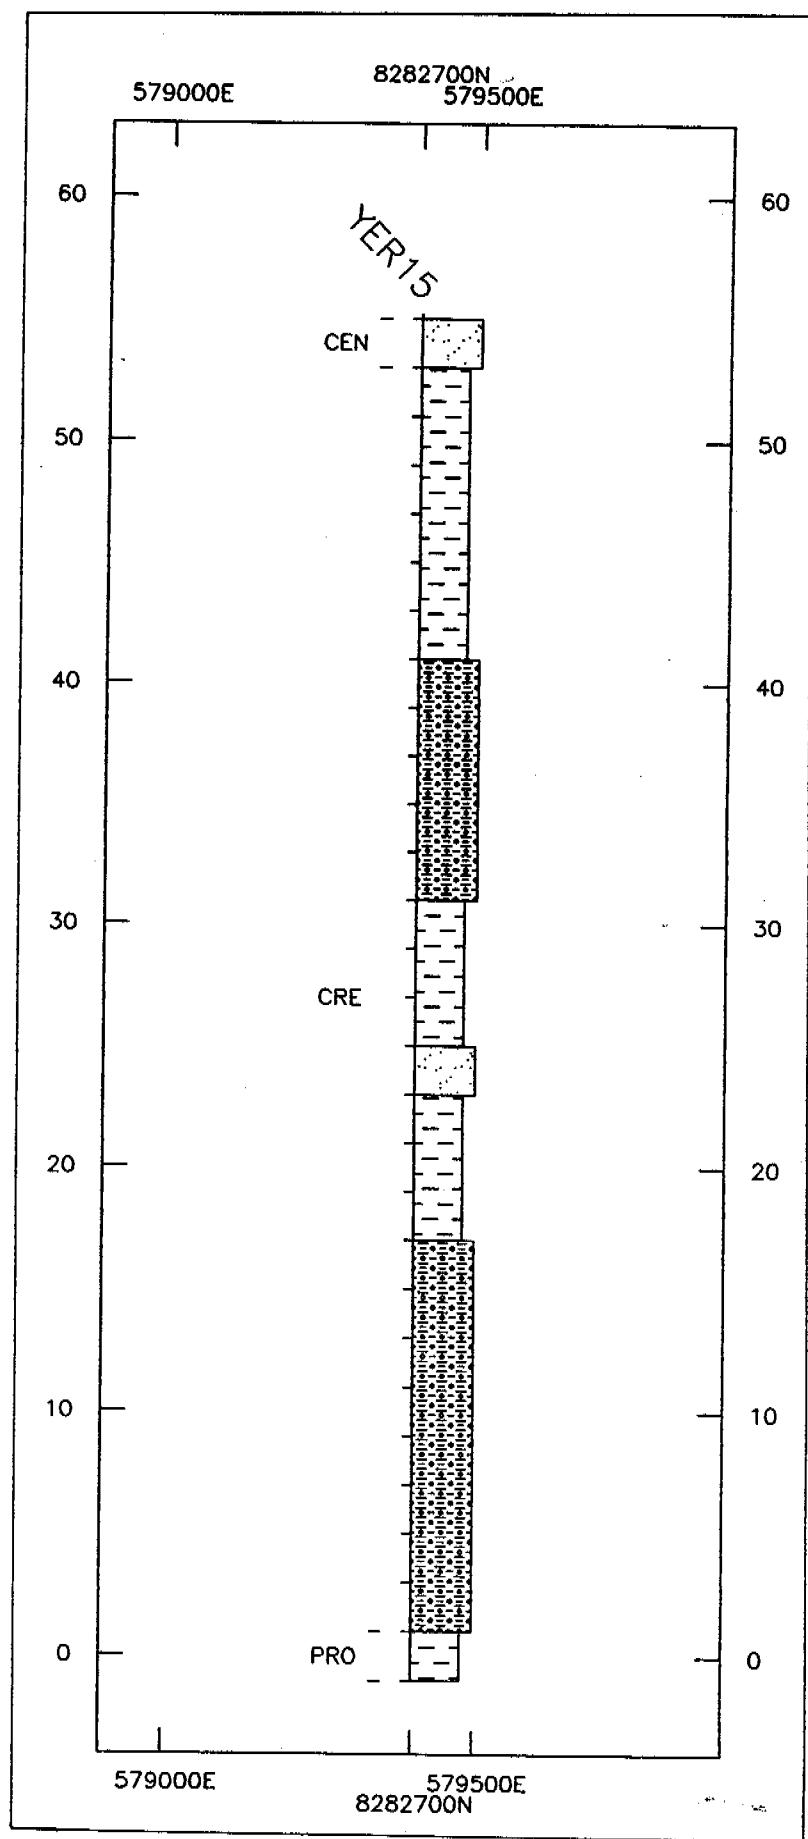

- MN1 <0.5% Mn Oxide
- MN2 0.5–5% "
- MN3 5–20% "
- MN4 20–30% "
- MN5 30–50% "
- MN6 >50% "

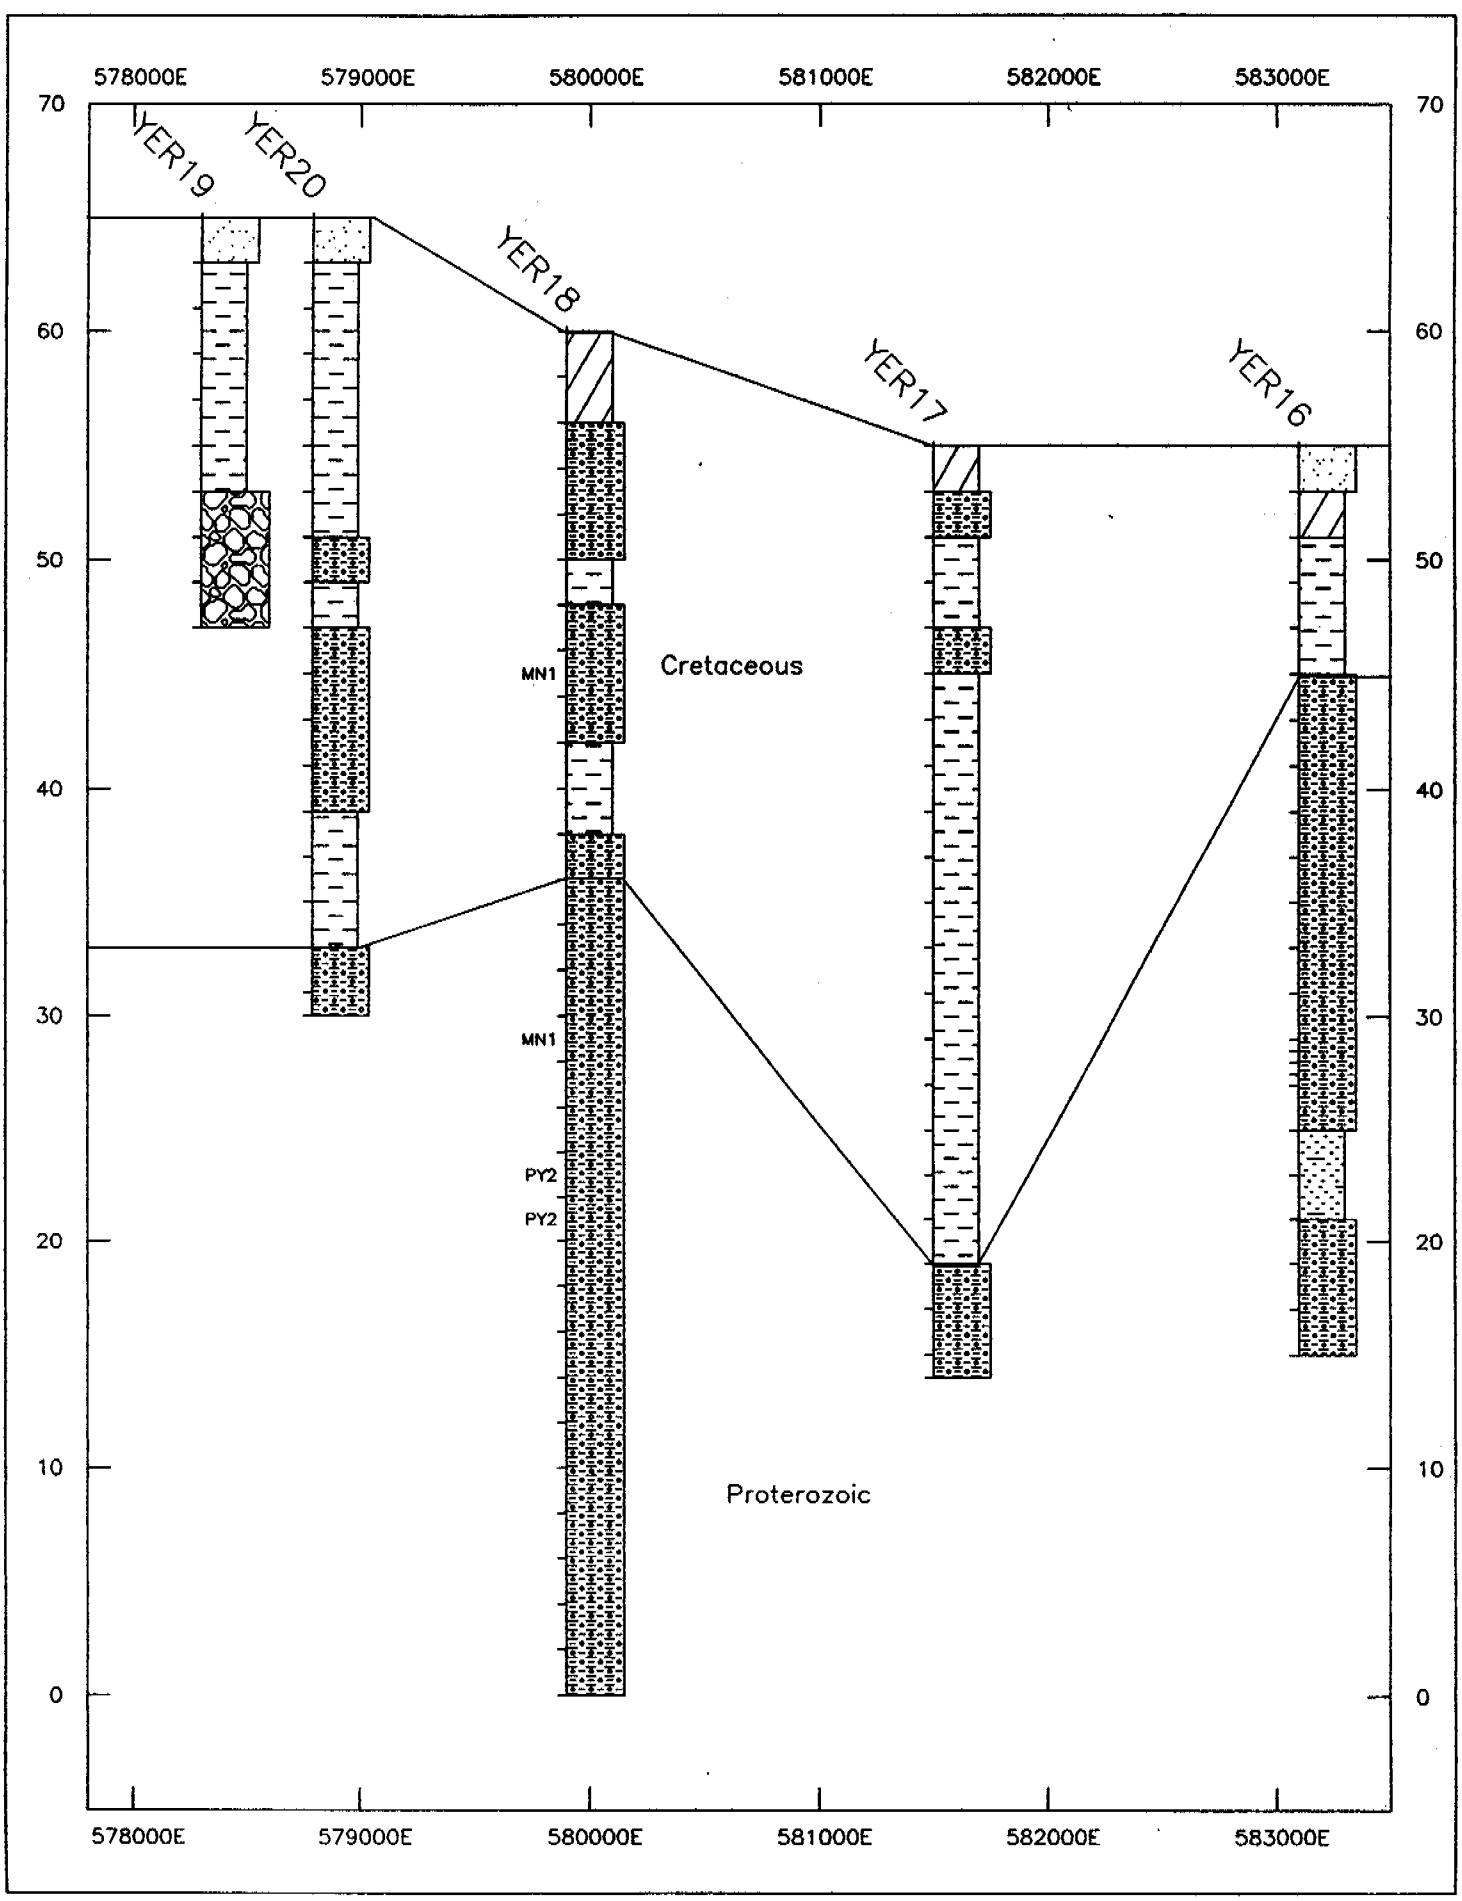

Scale: Scales vary between sections and are shown by tick marks in each section. All distances are in metres.

**APPENDIX 11.**

Statements of Expenditure

## **STATEMENT OF EXPENDITURE**

### **EXPLORATION LICENCE 7260**

For the period

24th May, 1994 to 23rd May, 1995

Geoscientist/Professional	34,020
Field Support/Office Staff	14,001
Other Contractors	755
Equipment	20,314
Vehicles	12,725
Helicopter Charter	4,371
Drilling	99,449
Geophysics	7,273
Surveys	8
Geochemistry	1,969
Laboratory	2,554
Drafting/Computing	667
Office Expenses	375
Library	61
Other	1,094
Sub-Total	199,636
10% Overheads	19,963
<b>Total:</b>	<b>\$ 219,599</b>

## **STATEMENT OF EXPENDITURE**

### **EXPLORATION LICENCE 7261**

For the period

24th May, 1994 to 23rd May, 1995

Geoscientist/Professional	17,585
Field Support/Office Staff	5,483
Other Contractors	309
Equipment	6,491
Vehicles	5,790
Fixed Wing Air Charter	2,826
Drilling	20,169
Geophysics	22,743
Survey	49
Geochemistry	1,400
Drafting/Computing	1,443
Office Expenses	247
Other	321
Sub-Total	84,856
10% Overheads	8,485
<b>Total:</b>	<b>\$ 93,341</b>

## **STATEMENT OF EXPENDITURE**

### **EXPLORATION LICENCE 7262**

For the period

24th May, 1994 to 23rd May, 1995

Geoscientist/Professional	13,084
Field Support/Office Staff	3,300
Other Contractors	270
Equipment	5,168
Vehicles	3,166
Helicopter Charter	3,292
Fixed Wing Air Charter	3,180
Drilling	3,389
Geophysics	36,681
Surveys	1,750
Laboratory	2,680
Geochemistry	1,750
Drafting/Computing	501
Office Expenses	551
Library	21
Other	267
Sub-Total	78,137
10% Overheads	7,813
<b>Total:</b>	<b>\$ 85,950</b>

## **STATEMENT OF EXPENDITURE**

### **EXPLORATION LICENCE 7263**

For the period

24th May, 1994 to 23rd May, 1995

Geoscientist/Professional	42,849
Field Support/Office Staff	20,533
Other Contractors	1,057
Travel/Accommodation/Meals	858
Equipment	9,689
Vehicles	8,365
Helicopter Charter	3,292
Fixed Wing Air Charter	5,654
Drilling	66,497
Geophysics	25,908
Surveys	1,868
Laboratory	4,801
Geochemistry	2,382
Drafting/Computing	923
Office Expenses	278
Library	21
Other	278
Sub-Total	195,745
10% Overheads	19,574
<b>Total:</b>	<b>\$ 215,319</b>

## **STATEMENT OF EXPENDITURE**

### **EXPLORATION LICENCE 7264**

For the period  
24th May, 1994 to 23rd May, 1995

Geoscientist/Professional	19,427
Field Support/Office Staff	6,771
Other Contractors	2,288
Field Supplies	1,269
Equipment	8,836
Vehicles	5,194
Freight/Storage	628
Helicopter Charter	2,186
Fixed Wing Air Charter	314
Drilling	12,513
Surveys	1,789
Geophysics	8,609
Laboratory	2,052
Geochemistry	967
Drafting/Computing	622
Office Expenses	289
Library	351
Other	496
Sub-Total	74,601
10% Overheads	7,460
<b>Total:</b>	<b>\$ 82,061</b>

## **STATEMENT OF EXPENDITURE**
