LOCATION MAP

SUMMARY

Exploration Licence 6289 was granted to Stockdale Prospecting Ltd on 1 December 1988 for a period of six years. It is the sole tenement remaining in the Roper River Joint Venture between Stockdale Prospecting Limited and Poseidon Exploration Limited.

The licence area was originally applied for to target economic diamond deposits, however more recent exploration has targeted base metal mineralisation.

This report details exploration within the remaining portion of the tenement prior to surrender on 8 November 1993 and summarises previous exploration.

Exploration has included:

- Stream sediment and loam sampling for diamonds;
- -80# stream sediment sampling for base metals;
- Grid soil sampling;
- IP and TDEM geophysical surveys; and
- Diamond drilling.

Results from the diamond exploration revealed six non kimberlitic ilmenite grains and a singleton diamond which was not repeated during follow up sampling. Base metal exploration of the Wongalara prospect resulted in the drilling of three diamond drill holes. Although weak Pb±Zn mineralisation was intersected, no further work is recommended.

The tenement was surrendered on 8 November 1993.

1. INTRODUCTION

Exploration Licence 6289 is the sole tenement remaining in the Roper River Joint Venture between Stockdale Prospecting Limited (SPL) and Poseidon Exploration Limited. The licence was granted to Stockdale Prospecting Ltd on 1 December, 1988 for a period of six years.

It was subsequently partially reduced on the 18 February 1991 and the 30 November 1992 and surrendered on 8 November 1993.

The area was originally applied for to target economic diamond deposits but more recent exploration has concentrated on base metal exploration.

2. CONCLUSIONS AND RECOMMENDATIONS

Conclusions

Potential diamond targets highlighted during reconnaissance sampling when tested were found to be unrepeatable.

Base metal exploration of the Wongalara prospect resulted in the drilling of three diamond drill holes. Although weak Pb±Zn mineralisation was intersected, no further work is recommended.

Recommendations

Surrender of tenement.

3. TENEMENT

Exploration Licence 6289 (Wongalara) was granted to Stockdale Prospecting Limited on the 1 December 1988 for a period of six years. In early 1991 Poseidon Exploration Limited entered into the Roper River Joint Venture with Stockdale Prospecting Ltd.

A statutory 50% reduction of the area was carried out during 1991 and 1992. Table 1 details the progressive reduction.

Table 1: Reduction of EL 6289

	<u>Blocks</u>	<u>Sq Km</u>
Original Area (1988)	500	1610
Reduced Area (1991)	339	1092
Reduced Area (1992)	170	547

4. LOCATION AND ACCESS

The licence area is located on Mainoru Station on the Urapunga (SD 53-10) 1:250,000 map sheet, Figure 1. It is centred 250 km east of Katherine. The unsealed Bulman road provides access to the project area. Access east from Mainoru Station is via station tracks over thick bulldust of the Mainoru River floodplain.

Access within the licence is by station tracks and across country and is limited during the wet season (commonly December-March). Within areas where topography is more rugged or east of the Wilton River, access is by foot or helicopter.

Access across the Wilton River to Wongalara prospect was established in 1992. Refurbishment is necessary after each wet season. Prior clearance of the route and drilling area was obtained from the Aboriginal Areas Protection Authority.

5. PHYSIOGRAPHY

The licence area is dominated by the Wilton River Plateau which is part of Stewart's (1954) physiographic classification of the Gulf Fall. It is a mature, dissected plateau of flat-lying sandstone capped, in places, by strongly jointed sandstone with variable laterite development.

The Wilton River and its tributaries cross the Plateau in well developed valleys up to 1-2 km wide. The margin of the plateau is best observed in the north of the licence area as it grades down to the east-flowing Mainoru River. Here it grades into the rounded hills and shallow dip slopes more typical of the Gulf Fall.

The Mainoru River and its extensive alluvial floodplain dominates the north of the licence area. The confluence of the Mainoru River and the south-flowing Wilton River occurs at the northern edge of the Wilton River Plateau near Herbert Bluff and is marked by an area subject to extensive inundation and numerous waterholes.

Small creeks draining the Wilton River Plateau often consist of a small gully containing rock jumble and boulders. Third order streams are generally sand-choked and are not suitable for sampling.

6. GEOLOGY

6.1 Regional and Tenement Geology

The tenement is situated in the north of the Urapunga 1:250,000 mapsheet (Throsby, 5769 and Benda, 5869, 1:100,000 mapsheets).

The detailed geology of the tenement area is relatively straight forward and is dominated by flat-lying to shallow-dipping, middle Roper Group sediments which unconformably overlie the McArthur Group and Mt Rigg Group, Figure 2.

The Crawford Formation is the basal unit within the licence area and outcrops extensively in the north. The Crawford Formation is generally a

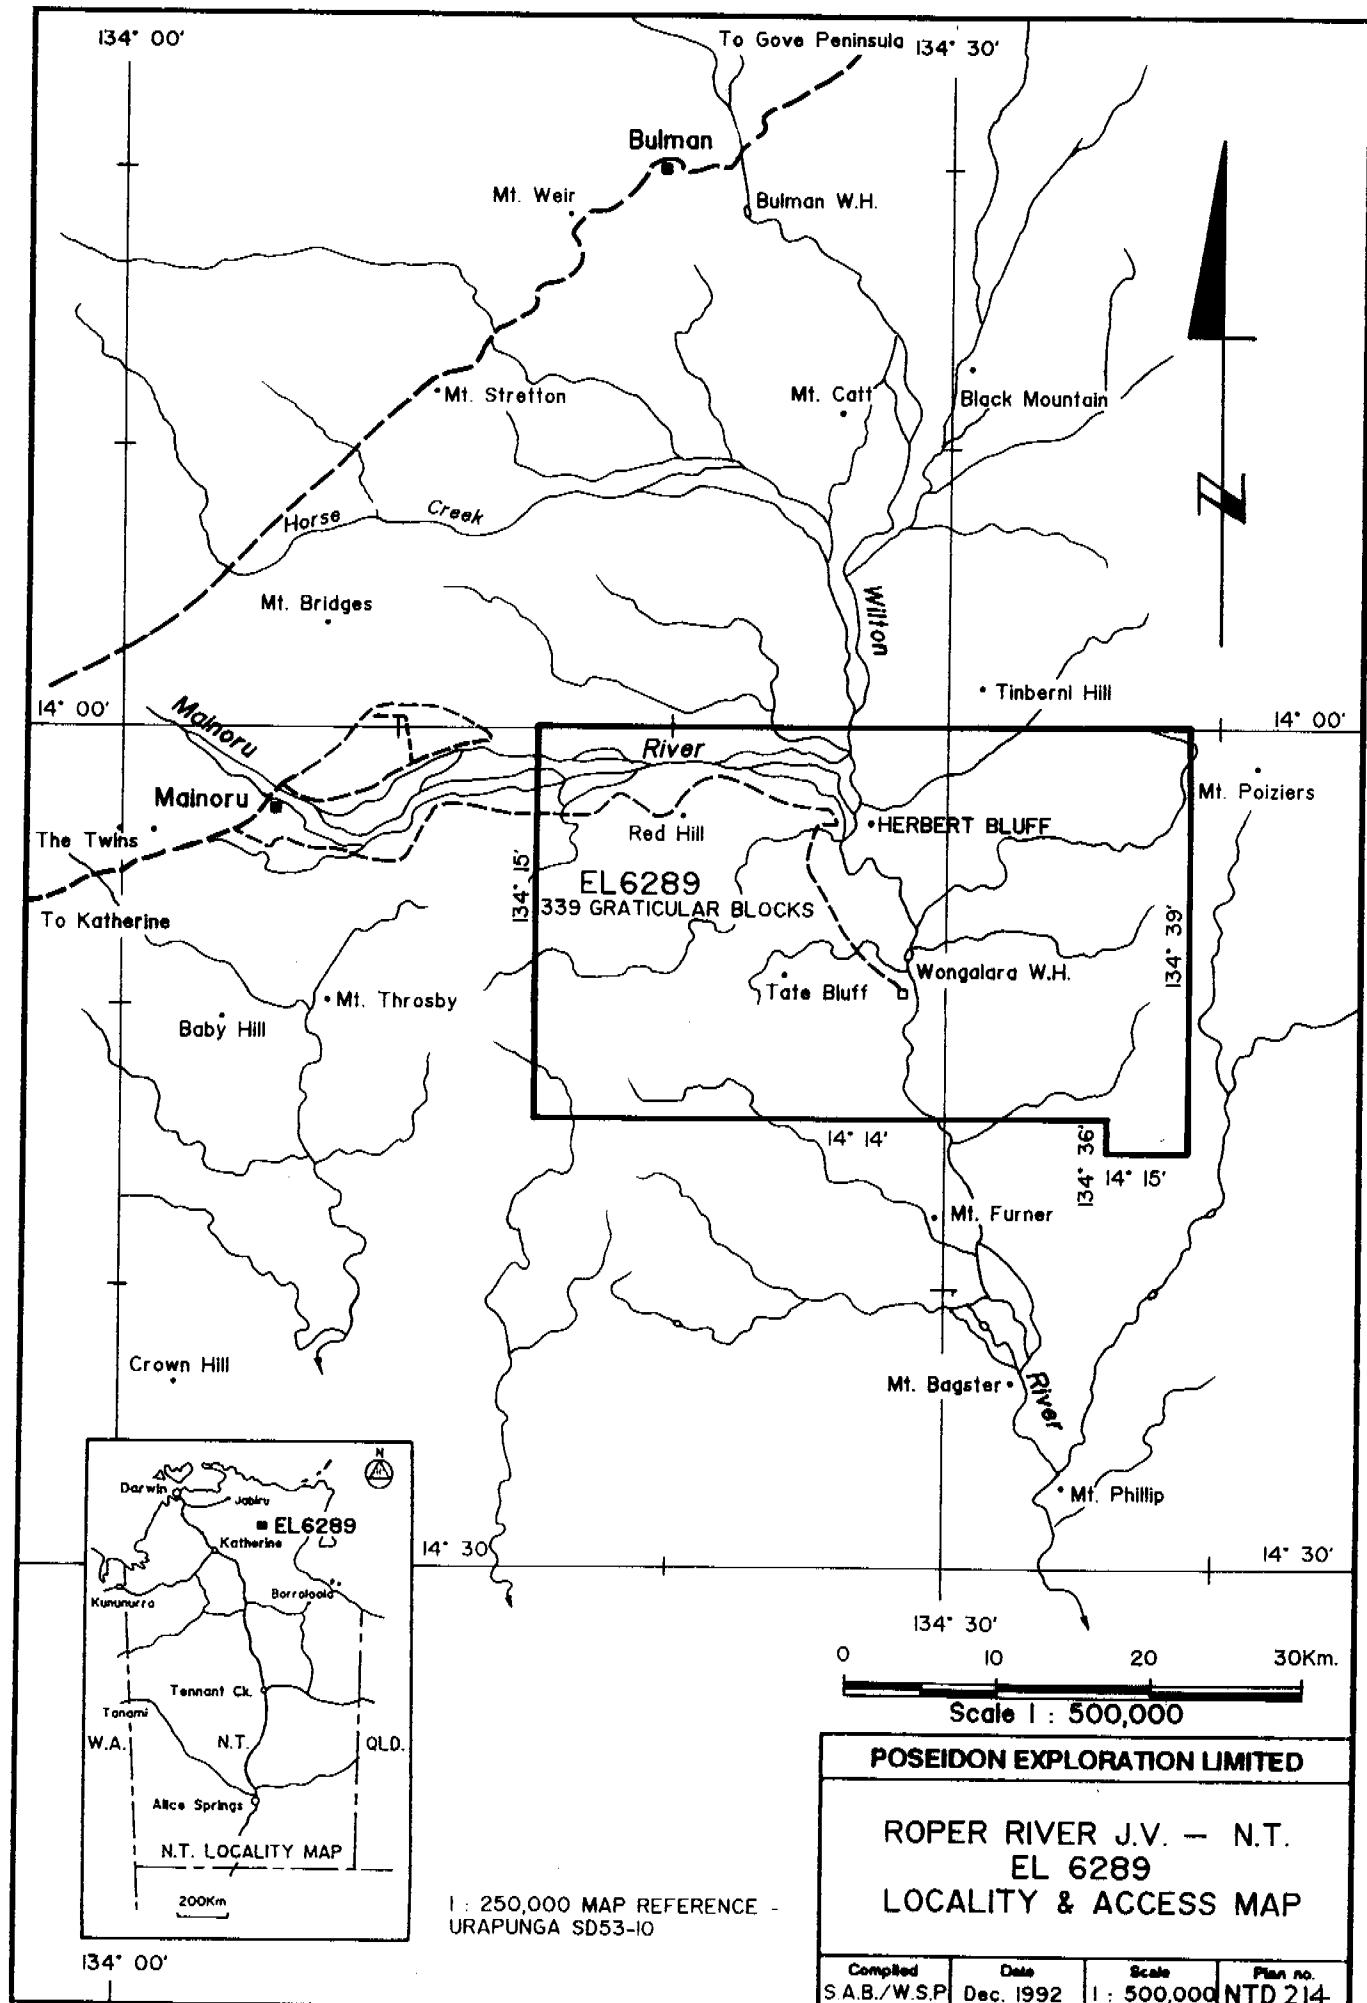

Fig. 1

pink and buff, micaceous, feldspathic, quartz greywacke with minor fine micaceous siltstone. Glauconite is a diagnostic mineral in the Formation.

The Abner Sandstone conformably overlies the Crawford Formation and is sub-divided into four conformable members, of which the uppermost three are represented in the licence area. The Jalboi Member consists of blocky and flaggy micaceous sandstone and greywacke, siltstone and shale and dominates the licence area.

The overlying Hodgson Sandstone Member is restricted to the southeast and southwest and is a relatively clean friable, massive to coarse sandstone with minor siltstone.

The Munyi Member is the uppermost member of the Abner Sandstone and has a restricted outcrop in the southeast of the licence. It consists of ferruginous sandstone and siltstone with minor shale.

The Roper Group sediments within the licence area are consistent with deposition in a gross fluvial environment alternating with short-lived, shallow marine transgressions, in places locally reducing.

Several dolerite sills have intruded the upper Roper Group and have an extensive distribution, particularly in the south of the licence area.

Cainozoic sand and alluvium represent much of the area's valley fill whilst a thin veneer of laterite is developed over ferruginous sandstone on the Wilton River Plateau.

The rocks are folded and faulted, although folding is poorly developed due to shallow burial depths. Most folding, where observed, appears to be adjacent to major faults.

Most external stress has resulted in faulting, particularly during the Precambrian, with the dominant fault trend being north or east. The Showell Creek Fault is the most prominent fault system and is observed in the east of the licence area. This fault system parallels the trend of the Batten-Walker Trough Zone observed in the adjacent mapsheet.

Minor north-east trending faults are present in the northwest of the licence area and appear to parallel the Mainoru Fault Zone.

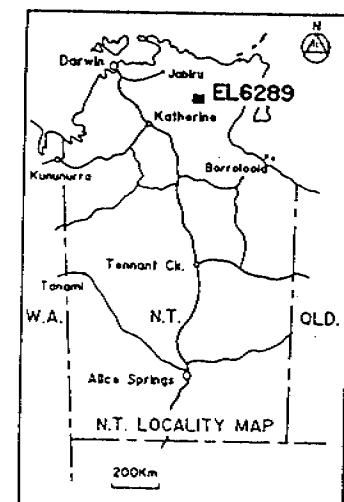

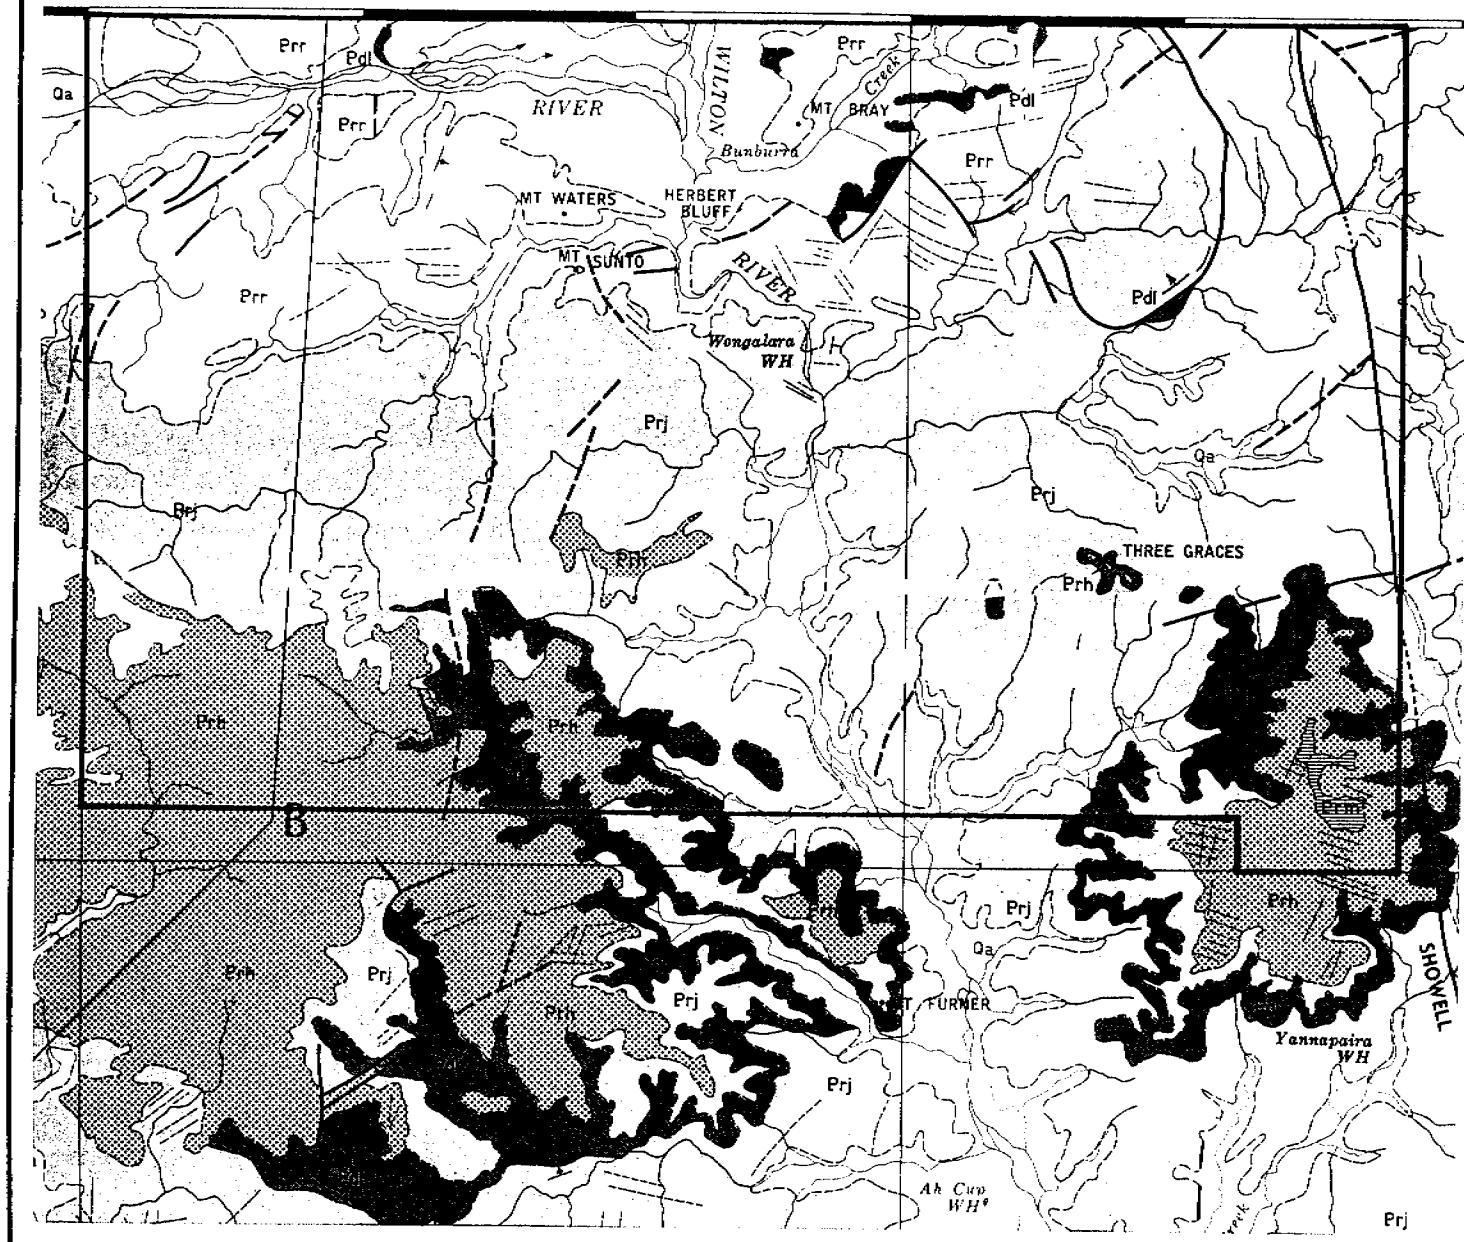

6.2 Mineralisation

No economic mineralisation has been reported within the project area.

At Bulman, (Mt Marumba SD 53-6) NNW of EL 6289, lead-zinc mineralisation was mined on an intermittent basis between 1908 and 1925. Enterprise Exploration (CRA) explored the immediate area during the late 1950's to early 1960's and developed a drill defined resource of 375,000 tons at 15% Zn and 2% Pb. Mineralisation at Bulman is associated with the Dook Creek Formation, locally remobilised by the Mt. Weir Dolerite.

Immediately east of Wongalara Waterhole (EL 6289) Anglo American Corporation of South Africa identified strongly anomalous lead and zinc geochemistry within ferruginous arkosic sandstones of the Jalboi Member, although no drilling was undertaken to assess the source.

7. EXPLORATION PROGRAMME 1989 - 1992

7.1 Diamond Exploration

Reconnaissance stream sediment and loam sampling was completed by SPL during the initial term of tenure.

During reconnaissance sampling a total of 99 stream samples and 9 loam samples were collected. A sample density of 1:10 sq km was attained.

The heavy mineral samples were sent to SPL's Darwin treatment plant and underwent primary concentration. Further concentration and mineral examination took place in the Company's laboratory in Melbourne. The results revealed six samples containing possible kimberlitic ilmenites and one sample containing a diamond.

The mineral chemistry of all ilmenite grains proved to be non-kimberlitic after microprobing.

The singleton 0.003ct diamond was followed up with 16 stream sediment samples. At each site 100 ltrs of stream sediment was excavated. A sample density of 1:1.3 sq km was achieved within the area of interest.

The follow up sampling failed to repeat the original positive result or detect a heavy mineral dispersion trail. The original diamond recovered was probably released from a secondary source horizon e.g. Cretaceous sediments.

Full details of these programmes, including maps, are reported in Podolsky (1990, 1991a, 1991b) and Price (1993).

7.2 Regional Base Metal Exploration

Stream sediment geochemical samples were collected in conjunction with the diamond sampling. An approximate sample density of 1:8 sq km was achieved.

All samples were screened to -80# by SPL and then forwarded to Anglo American Research Laboratories in Johannesburg, South Africa, for simultaneous 36 element analysis by XRF and Au/Pd analysis by Fire Assay.

All results were forwarded to geochemical consultants, Gilfillan Assoc., who were contracted to produce a regional geochemical interpretation and recommend areas for further work.

Full details of the geochemical programme are contained in the Common Reports to NTDME 31/1/90 for EL's 6286-6301 (Podolsky 1990), 31/1/91 for EL's 6286-6301 (Podolsky 1991a) and 31/1/92 for EL's 6287-6293 and 6296-6299 (Podolsky 1991b) and Booth (1991).

7.3 Wongalara Prospect

Wongalara prospect (Throsby 5769, GR 441397) was located by Australian Anglo American in the early 1980's through follow up of anomalous Pb/Zn values from stream sediment samples. Maximum

values were 40 ppm Pb and 30 ppm Zn. Follow up drainage sampling produced further anomalous values with maxima of 2500 ppm Pb and 1800 ppm Zn. The geochemistry defined two areas, one lying along a distinctive NNW-SSE trending lineament/fracture, with the other area located immediately north. Subsequent rock chip and soil sampling provided further encouragement with rock chip values to 2.2% Pb and 0.46% Zn.

Geological mapping revealed that the anomalous zones essentially consisted of a fault bounded plateau of shallow to horizontally bedded arkosic sandstone (Jalboi Member). The plateau is capped by 20 to 30 cm of laterite with well developed pisoliths up to 1 cm in size.

Crone EM was undertaken and a strong conductor associated with the northern gossan was interpreted. This was modelled as a shallow dipping, stratabound anomaly. The southern anomaly was interpreted to be fault related. Drilling was recommended but not undertaken.

Regional stream sampling was undertaken by Stockdale Prospecting Ltd during the 1990 field season with a geochemical sample taken at each diamond sample locality. This programme highlighted two zones of elevated base metal response (K and M). Drainage follow up of these areas concluded that the elevated Pb and Zn was related to laterite development over ferruginous Jalboi Sandstone.

Following Poseidon's entry to the project, the Wongalara prospect was re-located during the 1991 field season and a grid established for confirmatory mapping and detailed soil and rock chip sampling, Booth (1991). Access to the prospect was by boat. Grid soil and rock chip sampling defined a broad zone of anomalous Pb and Zn geochemistry. Approximate anomaly dimensions are 1400m x 450m, striking NE-SW. Maximum values returned were 2290 ppm Pb and 1190 ppm Zn for soil samples and 1.67% Pb and 2.3% Zn for rock chip samples. Anomaly definition was more pronounced for Zn than Pb (Booth, 1991).

The initial sampling programme was followed with infill sampling undertaken in conjunction with a Sirotem survey. Samples were collected at 25 metre intervals along the original lines to more accurately define the zone of anomalous soil geochemistry.

A Sirotem survey (fixed loop with roving vector receiver) was conducted over the northern zone of anomalous Pb-Zn geochemistry. The survey failed to identify any conductive response (Booth, 1991).

Following establishment of access over the Wilton River in late 1992, Search Exploration Services was contracted to conduct an IP survey over the zone of maximum geochemical response. This was completed in late October. Specifications for the IP survey were as follows.

Northern Grid Area

Two gradient blocks with 25 metre dipoles centred over the soil geochemistry anomalies:

Block 1:	Centred:	444400 E	8439700 N
	Coverage:	443900 E to 8439200 N to	444900 E 8440200 N

Block 2:	Centred:	445200 E	8440100 N
	Coverage:	444700 E to 8439600 N to	445700 E 8440600 N

One dipole-dipole (50 metre dipole) line across the best geochemical response, Line 445100 E, centred about 8440000 N.

Southern Area

A single dipole-dipole line across the postulated "fault controlled" geochemical response on Line 444,300 E.

Details of IP survey specifications are as follows.

	Dipole Dipole	Gradient Array
Receiver	Scintrex IPR-12	Scintrex IPR-12
Transmitter	Scintrex TSQ-4 (12kvA)	Scintrex TSQ-4 (12kvA)
Configuration	Dipole Dipole	Gradient Array
Method	Time Domain	Time Domain
Frequency	0.125Hz	0.125Hz
Current Electrode Separation	50m	
Dipole Spacing		50m
Operator	Search Exploration Services (SES)	SES
Date of Collection	September 1992	September 1992

8. EXPLORATION PROGRAMME, 1993

The IP data was re-processed in early 1993 and provided better definition of a coincident chargeability-apparent resistivity anomaly fringing the zone of maximum geochemical response (Maps 1 and 2). The dipole dipole data is presented in Figure 3.

Thompson Drilling, NT was contracted to complete three diamond drill holes to test the resistivity/chargeability anomaly (WD-1) and maximum soil/rock chip results (WD-2,3).

Hole details are summarised as follows.

Hole	Collar Easting	Collar Northing	Dip	Azimuth	TD
WD-1	444 500	8 493 960	-90°	0°	108.5m
WD-2	445 100	8 440 020	-90°	0°	80.0m
WD-3	444 500	8 439 650	-90°	0°	80.0m

Drill logs are presented in Appendix 1 whilst assay data is presented in Appendix 2. Drill hole collars are shown in Figure 4, whilst drill hole sample numbers and lithologies are presented in Maps 3 and 4, respectively.

A fillet of core was taken from each three metre interval for geochemical analysis and analysed by Amdel Laboratories, Darwin for the following elements.

Element	Pb	Zn	Ag	Fe	Mn	Mo	Mg
Detn limit	2	1	0.1	5	2	0.5	10
Units	ppm						
Scheme	AA1M	AA1M	AA1M	AA1M	AA1M	AA1M	IC3E

Better assay results from the geochemical sampling were as follows.

WD-2 9.1m @ 5600ppm Pb, 5140 ppm Zn, from 0m
WD-3 3.1m @ 2670 ppm Pb, 4220 ppm Zn, from 0m
 6m @ 4150 ppm Pb, 1800ppm Zn, from 15.1m
 6m @ 1460ppm Pb, 1665ppm Zn, from 57.1m

Following receipt of geochemical results, selected intervals of $\frac{1}{2}$ core were analysed by Amdel Laboratories, Darwin for the following elements.

Element	Pb	Zn	Ag	Fe	Mn
Detn limit	2	1	0.1	5	2
Units	ppm	ppm	ppm	ppm	ppm
Scheme	AA1M	AA1M	AA1M	AA1M	AA1M

Better assay results were as follows.

WD-2 1.5m @ 1.26% Pb, 0.97% Zn, from 2.6m
WD-3 2.0m @ 0.57% Pb, 0.45% Zn, from 15.6m

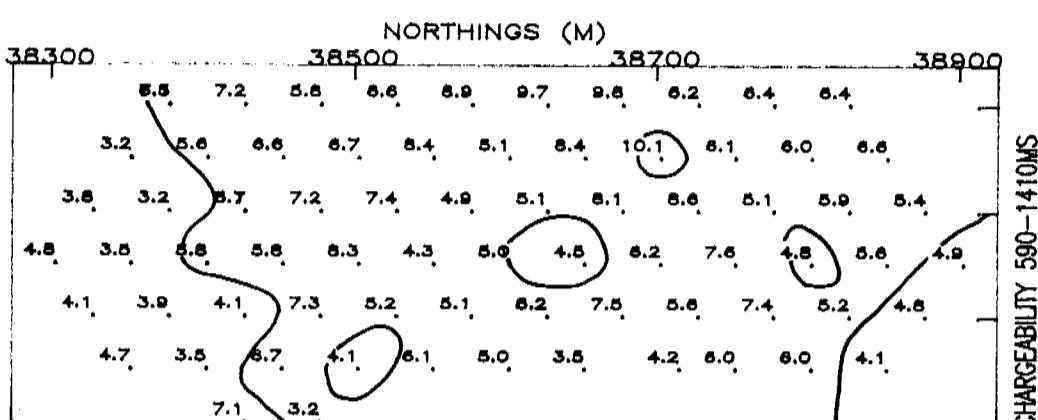

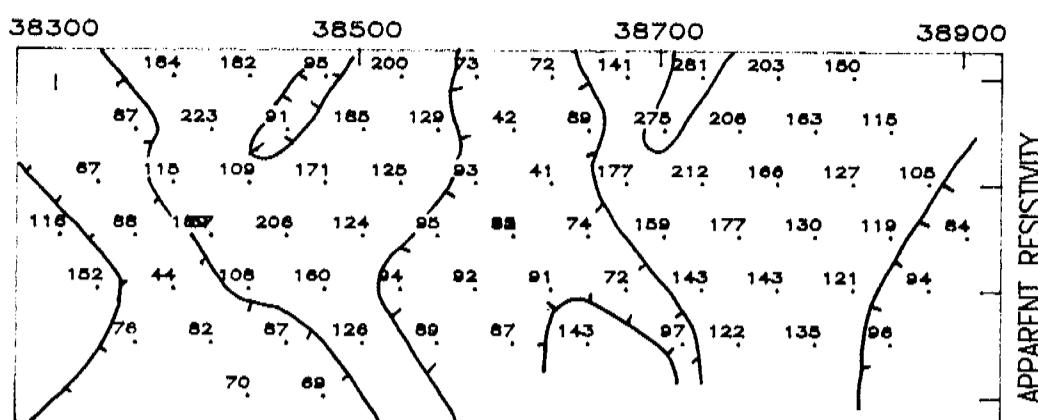

The better mineralisation was located in a light grey/green-light brown fine grained, micaceous sandstone with minor siltstone laminae. Ave 2-5% feathery Fe/Mn Ox after ?sulphide, locally up to 10%.

Five core samples from WD-1, drilled on the IP target, were submitted to Systems Exploration (NSW) Pty Ltd for a range of physical parameter testing. Summary details are as follows.

Sample	Depth	Lithology
#1	11.3m	Banded f grnd sst with pyrite vns & clots
#2	24.6m	F grnd silty sst with py clots
#3	25.3m	F grnd silty sst with py clots
#4	58.1m	F grnd x-bedded sst with slst, py clots & dissems
#5	82.8m	F grnd sst with dolm vns & carb. slst
#6	107.0m	F grn sst with lam & wispy carb. slst

The report from Systems Exploration (NSW) Pty Ltd is presented in Appendix 3. The contrast between the IP effect in samples #3, #4 and #5 is considered sufficient to produce the IP results observed from the gradient array survey.

Sample #4 was taken from 58.1m depth. Assay results at and around this depth were particularly low, although minor disseminated pyrite was observed.

DATA ACQUISITION & PRESENTATION

Operator : Search Exploration Ltd.

Transmitter : Scintrex TSQ-4

Receiver : Scintrex IPA-12

Timing : 2 secs on-off

Disco size : 60

Survey Date : Nov '92

Block centres :

Block centres :
Block 1 444, 400E 8, 439, 700N
Block 2 445, 200E 8, 440, 100N

Contour Interval : 10 ohm meters

1: 250,000 SHEET SD53-10
