Nickel Search - Mt. Hay Authority to Prospect 2716, Northern Territory

INTRODUCTION

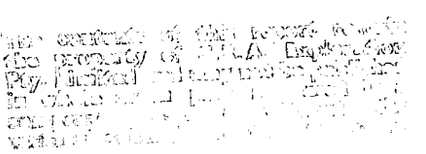
In the search for ultrabasics in the Alice Springs area 385 square miles were granted to the company in June, 1970. The A. to P. area covers one aeromagnetic anomaly (Bureau of Mineral Resources survey 1965(1)), with a maximum total magnetic intensity of 3,100 gammas. The area is partly covered by outcrops (Arunta Complex), partly by sand (alluvium). However, due to the presence of mafic and ultramafic rocks in the area, the outcrops extending west of the A. to P. area were also investigated.

The A. to P. expired on 7th June, 1971, but the area was re-applied for on 22nd June, 1971 in view of the possible uranium potential of the region.

The geochemical field work was initially carried out by a helicopter survey (October, 1970), followed by ground work in June, 1971.

GEOLOGY

The area was initially mapped by the B.M.R.(2) as part of the Arunta Complex. Later investigation has,



however, revealed less resemblance in lithology with the Arunta Complex generally in the vicinity (gneisses, amphibolites, mica-schists, etc.).

The outcrops consist of assemblages of black ferromagnesian and white felsic minerals in approximately equal proportions. They are free from foliation. Recrystallisation has occurred at a very high grade of metamorphism. Some garnet is present.

Three rock samples from the Mt. Hay-Mt. Chapple area have been described as pyroxene granulites.

PROCEDURES

Stream Sampling: (-80, +10 mesh) taken from helicopter covering approximately 80 square miles of outcrops with a density of 1 sample per 3 square miles.

Rock Sampling: collected from magnetically high areas.

Assays: for Cu, Ni, Pb, Zn, Co, Cr, Mo, W and U (-80 mesh) and analysed by The Zinc Corporation Limited and AMDEL (rock samples by spectrographic analysis). The coarse fraction (+10 mesh) from six of these samples was examined by Central Mineralogical Services for rock fragment and mineral identification (see attached CMS report number 70/12/15).

Follow-up Work: mainly tracing sources of the geochemical anomalies, by additional stream sampling and ground inspection of outcrops.

Water Sampling: collected from bores in the vicinity and analysed for U by The Zinc Corporation Limited.

Auger Test Drilling: (Gemco Auger Drill) carried out in an attempt to reach water table and/or bedrock. The drilling program was initiated on the strength of significantly anomalous uranium content in the water of a number of bores in the Napperby sheet area some 30 miles north of the present area, where Tertiary sediments overlie basement rocks. It was hoped to establish the southern margin of this Tertiary basin in the Mt. Chapple-Mt. Hay area. (?)Tertiary bedrock was encountered in two holes. Although no radioactivity was encountered by scanning the drill cuttings, samples collected over 6 feet intervals will be forwarded to The Zinc Corporation Limited for U and Th analyses, and the drillholes will be probed with a gamma logger. Evaluation will continue as results become available.

RESULTS

In terms of interpreting the stream sample values (-80 mesh) the total number of samples collected in the Arunta Complex of the Hermannsburg/Alice Springs 4 miles sheet area were taken into consideration. Of a total number of approximately 900 samples the top 5% of values, in terms of numbers, were considered probably anomalous (above the threshold), i.e. between 5% and 7.5%.

Eighty per cent of the samples from the Mt. Hay area appeared to be Ni anomalous (above the threshold = 22 ppm Ni) and 50% Cu anomalous (threshold at 15 ppm). Co and Cr followed the same pattern as Ni. No erratic values were recorded.

However, the subsequent field investigation did not show up anything worth further pursuit in this area.

The pyroxene granulite specimens consist mainly of 35% two-pyroxene, 45% plagioclase, 15% quartz. The remaining 5% was microcline, opaques (including magnetite), garnet and apatite. Traces of hornblende and biotite were also recorded. The coarse fraction (+10 mesh) was also described as two-pyroxene granulite.

All the mafic/felsic rocks were generally magnetic.

A uranium investigation of bore water was carried out in connection with auger drilling in June/July, 1971. Along the northern border of the outcrop 3 holes were sunk with a Gemco auger drill. Drill cuttings were sampled at 6 feet intervals, but analyses have not yet been received. The bore water samples examined by The Zinc Corporation Limited were not anomalous.

Karanji Bore	<1 ppb U

Twin Bore	1 "
Mt. Hay Bore	<1 "
Valley Bore	1 "
Limestone Bore	2

CONCLUSIONS

Since the pyroxene granulite probably represents a basic igneous rock, a higher base metal content relative to the more acid rocks and metasediments of the Arunta Complex generally is a reasonable expectation.

No further work on the basement rocks in the area of the A. to P. is recommended, but it is proposed to continue investigations in the younger sediments in the search for uranium.
