1:100, 000 map sheet: Doreen (5153) and Yuendumu (5253)

Bibliographic Data Sheet

Project Name:	Ngalia Thrust.
Tenement Numbers:	EL24566.
Tenement Operator:	Uranium Exploration Australia Limited.
Report Type:	Annual Technical Report.
Report Title:	Annual Technical Report on EL 24566 for the period 21 October 2008 to 20 October 2009.
Report Period:	21 October 2008 - 20 October 2009
Author:	J. Cherry
Date of report:	9 November 2009
1:250, 000 map sheet:	MOUNT DOREEN SF52-12
1:100, 000 map sheet:	Doreen 5153, Yuendumu 5253
Target Commodity:	Uranium
Keywords:	Ngalia Thrust, Uranium, Ironstone, Greisen, Southwark Granite Suite, Diamond drilling, Radiometrics, Magnetics, Geochemistry, Prompt Fission Neutron (PFN), Gamma, Anomaly B, U ² /Th ratio, Miarilitic texture.
Prospects drilled:	Crystal Creek Anomaly A.
List of Assays:	Al ₂ O ₃ Ag As Au Ba CaO Ce Co Cr Cu Dy Eu Er F Fe ₂ O ₃ t FeO Gd Ho K K ₂ O La LOI Lu Mn MnO Mo Na ₂ O Nb Nd Ni P P ₂ O ₅ Pb Rb S Sb SiO ₂ Sm Sn Sr Ta Tb Ti TiO ₂ Th U V W Y Yb Zn Zr.
Abstract:	
Location:	EL 24566, "Ngalia Thrust" is located approximately 320km northwest of Alice Springs in the Northern Territory. The tenement is situated on the boundary of the Doreen (5153) and Yuendumu (5253) 1:100,000 map sheets within the MOUNT DOREEN 1:250000 map sheet.
Geology:	The geology comprises Palaeoproterozoic metamorphic and igneous rocks, intruded by the Mesoproterozoic Southwark Granite suite which is in turn overlain by the Neoproterozoic to Palaeozoic sedimentary units of the Ngalia Basin.
Work done:	Exploration comprised 9 diamond holes for a total of 1014m, assay of 374 core samples, downhole logging of 7 drill holes using Prompt Fission Neutron (PFN) and gamma tool, field mapping, assay of 38 rock chip samples, QEMSCAN analysis of selected field samples, detailed airborne radiometrics/magnetics and a soil sampling over Anomaly B for a total of 599 samples.
Results:	Drilling at Anomaly A failed to intersect any significant uranium mineralisation. Field mapping and reinterpretation of the 2007 airborne radiometrics lead to the discovery of a uriniferous ironstone lode structure up to 3km in strike length outcropping at surface in an area referred to as Anomaly B. Best results from rock chip samples of the ironstone lode include 4,000ppm and 3,600ppm U.

Conclusions:

Use of the radiometric U²/Th ratio proved very successful in highlighting the Anomaly B region as a potential site for uranium accumulation. The evident structural control over deposition of the ironstone lode at Anomaly B suggests the potential for further mineralised structures located beneath recent (Quaternary) cover sediments, which is further supported by detailed magnetics over the northwest corner of the tenement. A drilling program comprising ~2,500m RC drilling is planned to further test the main ironstone structure at Anomaly B and will commence during November 2009.

Summary

Drilling at the Anomaly A prospect comprising 9 diamond drill holes was completed in December 2008 for a total of 1,014 metres. A total of 374 half core samples taken at varying intervals were subsequently submitted for chemical assay and 7 of the holes were logged using down hole Prompt Fission Neutron (PFN) and gamma methods.

Assay results from the 2008 drilling program were disappointing, with the best result being 1m @ 176ppm U (08CC07, 30-31m) taken from a heavily altered granite at the margin of a heavily altered mafic intrusion. Results obtained from the PFN tool were erratic due to uranium concentrations being below PFN detection limits, with the gamma logs providing the best correlation with assay data.

Reprocessing of the 2007 airborne radiometric data was carried out to produce a U^2/Th image over EL 24566, which strongly highlighted the area referred to as Anomaly B. Subsequent field investigation led to the discovery of an outcropping uraniferous ironstone lode approximately 3km in strike length, which varies in width from ~30cm to several metres with an average width of ~2m. Using a portable Niton XL3t XRF analyser in the field, the best assay results from the ironstone lode included 3500ppm U (± 209) at location 83006, 2644ppm U (± 174) from location 83009 and 1438ppm U (± 140) from location 83011. Subsequent laboratory XRF analysis of approximately corresponding samples yielded 4000ppm U, 3600ppm U and 700ppm U respectively.

QEMSCAN analysis was conducted on two ironstone samples (83006 & 83009). The results of this work suggested that the uranium was hosted by Ti-Fe oxides (up to 5% U) while complex Rare Earth Element phases could host between 1-30% uranium. However, the results of this work were considered largely inconclusive due to complex mineral textures and intergrowths making unambiguous $U/Th/REE$ mineral identification difficult. These samples were subsequently submitted for Scanning Electron Microscopy (SEM) work at the University of Adelaide, results are pending.

The ironstone is hosted by felsic intrusive rocks which outcrop throughout the Anomaly B region. These lithologies range from fine grained, quartz-feldspar porphyry to a coarse, equigranular granite. The porphyritic rock type contains varying levels of miarolitic texture and appears to be responsible for producing the U^2/Th anomaly in the region, with an average of 48ppm U and 23ppm Th obtained from 12 rock chip samples.

A high resolution airborne radiometric and magnetic survey was conducted during September 2009 over the northwest corner of the tenement, encompassing both Anomaly A and Anomaly B. This survey comprised a total of 1,913 line kilometres at a line spacing of 25m and sensor height of 20m. The resulting radiometrics both confirmed and better defined the U^2/Th anomaly at Anomaly B, while interpretation of the magnetics suggests the potential for further ironstone structures beneath cover and several attractive magnetic targets which coincide with interpreted structural trends in the area.

A soil sampling survey was conducted during October 2009 comprising 20 north-south oriented sampling lines at 200m line spacings with 20m sample intervals. A total of 599 samples were collected and submitted for assay. Results from this survey indicate that elevated Cr, Co, Ni, Ti and V values correlate well with the main ironstone lode and would be useful pathfinder elements for future soil surveys. Conversely, areas of elevated Ta and Nb, coupled with areas of low overall Ti seem to be the best indicators for the greisen alteration. The maximum uranium value obtained from the survey was 29ppm with an overall average of 10ppm U. Further work is also being carried out to confirm the validity of an elevated uranium soil anomaly which sits outside the major radiometric U^2/Th anomalous regions.

1. Introduction

EL 24566, "Ngalia Thrust" is located approximately 320km northwest of Alice Springs in the Northern Territory. The tenement is situated within the MOUNT DOREEN 1:250,000 map sheet and covers an area of 242km².

The tenement is accessed via the Tanami Track from Alice Springs and the unsealed Vaughan Springs Station access road (Figure 1). Access within the tenement is via existing station tracks and fence boundaries.

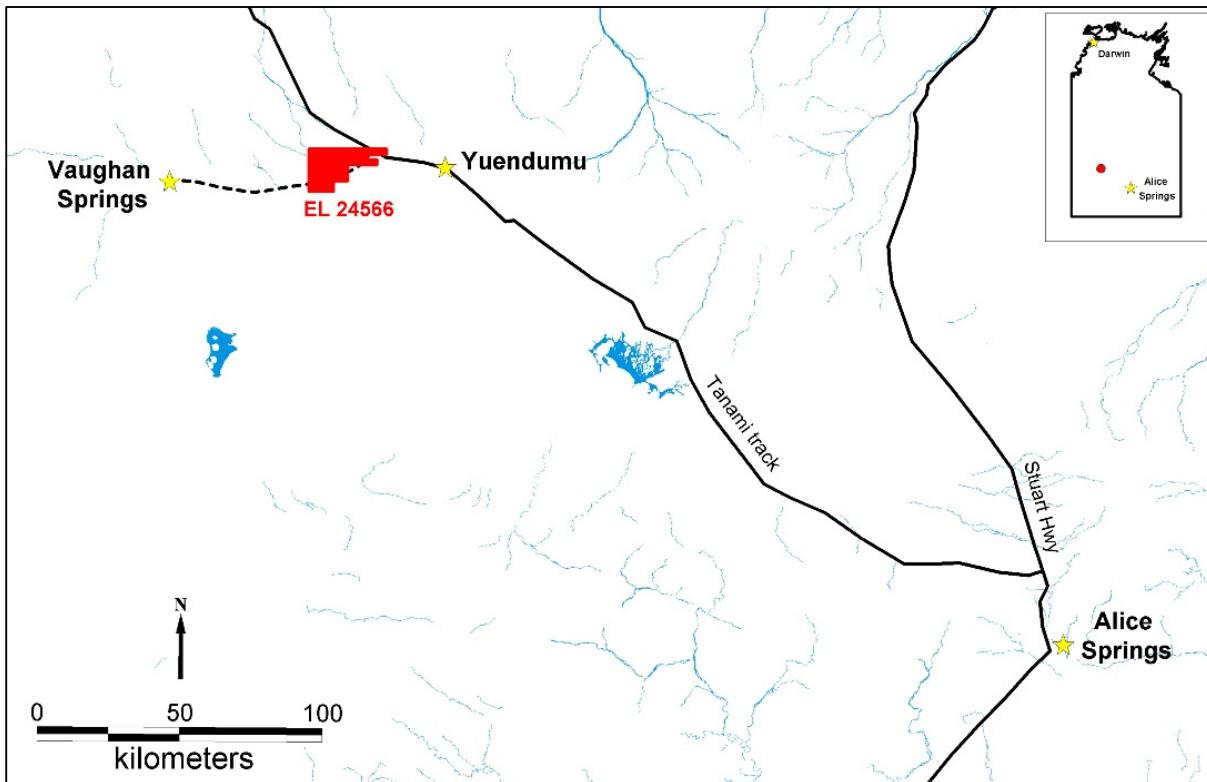

Figure 1: EL 24566 "Ngalia Thrust" project location.

1.1 Tenure

Exploration Licence 24566, registered in the name of Uranium Exploration Australia Limited (UXA) was granted 21 October 2005 for a term of 6 years.

1.2 Climate, vegetation and physiography

EL 24566 lies in an arid to semi arid rainfall belt receiving between 200mm and 250mm of rain per annum. The wet season is usually between the months of November and February. Temperature variation of greater than 38°C in summer to 0°C in winter has been recorded. The tenement lies within the Burt Plains bioregion.

Topography within the exploration licence is generally flat and much of the ground is covered by Mulga scrub. Several rock outcrops within the area are generally of low relief.

2. Previous Exploration

Prior to 1977 the only geological mapping undertaken in the region was in 1967 to compile the MOUNT DOREEN 1:250,000 Sheet (SF52-12).

During the 1970's Central Pacific Minerals (CPM) conducted track etch surveys on EL 605 (Yuendumu) in the vicinity of EL 24566. A total of 100 radon detection cups were laid and recovered along 5 traverses. Three 30m deep percussion holes were subsequently drilled on and around radon anomalies. Drilling failed to identify the source of the radon anomalies, however CPM suggested they could be caused by either uranium mineralisation, drainage (both surface and sub surface) or local radon producing concentrations of radioactive minerals. However, CPM's main interests centred on radiometric anomalies within outcropping Mt Eclipse Sandstone.

Detailed geological mapping was undertaken in 1977 by Afmeco over EL 1321 located immediately to the west of EL 24566, covering the areas of the Dingo's Rest and Rankins Reward uranium prospects.

Exploration between 1997 and 1999 by CRA/Rio Tinto on EL 9413 (Annie Spring) covered the northern unconformable contact between metamorphic rocks and granite intrusions of the Palaeoproterozoic Arunta Block and the Neoproterozoic to Carboniferous sediments of the Ngalia Basin (Davies, 1998). Exploration was focused on base metal and gold mineralisation, with uranium targets considered a secondary priority. Four magnetic anomalies were targeted for associated iron oxide, base metal and gold mineralisation. Further modelling produced two priority targets, AS1 and AS2.

Magnetic anomaly AS1 was tested by drill hole DD97AS001 in 1997 to a final depth of 177.9m, intercepting megacrystic granite to a depth of 111m and highly magnetic BIF from 111m to EOH. The BIF was interpreted as a "raft" within the granite, and subsequent geochemical assay failed to produce any anomalous results.

Magnetic anomaly AS2 was tested with drill hole DD97AS002 to a final depth of 251.8m, intersecting siltstone, fine sandstone and four BIF zones up to 9m wide. The BIF was magnetite rich with chert veins and pervasive chlorite alteration. Associated pyrite assays returned 1100ppm As, 0.1g/t Au and 0.49wt% P. It was concluded that the Mg-chlorite alteration and hematite cherts associated with reactive lithologies shared strong similarities to the Kintyre uranium deposit in WA. Subsequently, the potential for uranium was upgraded and the licence was covered by a detailed airborne radiometric and magnetic survey (Davies, A., 1999).

Interpretation of the radiometric data revealed four zones related to distinct lithologies. Fifty-one radiometric anomalies were identified, of which nineteen were followed up on the ground:

- Zone 1 comprised the Mt Eclipse Sandstone and included the Bigrlyi deposit; seven anomalies were rock chip sampled but no significant mineralisation was identified.
- Zone 2 comprised the naturally elevated Patmungala Beds which did not warrant any further work.
- Zone 3 comprised anomalies sourced from the Yaloogarie Granite. One hot spot anomaly sampled returned 2550ppm U and was associated with carnotite.
- Zone 4 was focused on contact zones between the Patmungala Beds and the Yarunganyi Granite. Six anomalies were followed up with visible torbernite observed within a narrow ferruginous quartz filled fracture. No significant mineralisation was located and the tenure was subsequently relinquished.

Work conducted by UXA since the commencement of tenure has included:

- 2005 - 2006. UXA conducted preliminary field investigations, collecting a total of nine rock samples which were assayed for uranium and base metals. The best result was 25ppm U from sample Ngalia-4, a megacrystic feldspathic granite. The highest scintillometer reading was located at Ngalia-8 (1240 cpm) in pegmatitic granite with possible secondary uranium fracture coatings. Most samples were of the highly differentiated Yarunganyi Granite and showed elevated radiometric activity (Sawyer 2007).
- 2006 - 2007. GPX Ltd was commissioned by UXA to conduct a detailed airborne radiometric and magnetic survey over EL24566. The survey comprised a total of 2658 line kilometres at 100m line spacings covering the entire tenement. Interpretation of the data revealed a number of uranium only anomalies, along with several major structural trends not previously mapped on the MOUNT DOREEN 1:250,000 mapsheet. The high intensity magnetic anomaly previously referred to as AS1 by CRA/Rio Tinto was clearly evident in the southern portion of the tenement.
- 2007 - 2008. Several field mapping trips were conducted during the reporting period, along with petrography on 10 field samples and assay work for 16 rock chip samples collected mainly around the Anomaly A area. The best assay result yielded 310ppm U (sample # NT109) from a heavily kaolinised granite. Planning for the late 2008 drilling campaign at Anomaly A was also carried out.

3. Geology and Mineralisation

The regional geology comprises Palaeoproterozoic metamorphic and igneous rocks (Lander Rock beds, Reynolds Range Group, Patmungala Beds, Carrington Granite Suite), the Mesoproterozoic Southwark Granite Suite and the Neoproterozoic to Palaeozoic sedimentary units of the Ngalia Basin (Figure 2).

The Lander Rock beds are interpreted to be older than 1880Ma and comprise pelitic & psammitic turbiditic schist and gneiss with minor metabasalt or metadolerite, with metamorphic grade ranging from greenschist to transitional granulite facies. The Reynolds Range Group unconformably overlies the Lander Rock beds and comprises epidotic calc-silicate and calcerous rocks, quartzite, pelitic and psammitic schists and mafic volcanics. The group has an interpreted age between 1780-1820Ma with metamorphic grade ranging from greenschist to amphibolite facies (Young, 1995).

The Patmungala Beds comprise a fault bounded sequence of sandstone and felsic volcaniclastic siltstone and has been dated at 1799 ± 9 Ma (U-Pb zircon). The Carrington Granite Suite intrudes the Lander Rock beds and comprises variably foliated granodiorite, tonalite and granite. A U-Pb zircon age of 1779 ± 6 Ma has been obtained for this suite (Young, 1995).

The Mesoproterozoic Southwark Granite Suite is the dominant rock type within EL 24566 and comprises five members; undivided Southwark Granite, Rapakivi Granite, Wakurlpa Granite, Yarunganyi Granite and Ethel Creek Granite. The suite is dated at around ~ 1570 Ma and intrudes the Lander Rock beds, Reynolds Range Group and Patmungala Beds (Young, 1995).

The Ngalia Basin is a large 300 km by 70 km east-west elongate intracratonic basin covering an area of $15,000\text{km}^2$. The Basin consists of approximately 6000m of Neoproterozoic and Palaeozoic sediments, which are thickest near the northern margin of the basin. The sequence consists of Neoproterozoic to Ordovician shallow marine and fluvial to glacial clastic, carbonate and evaporitic rocks.

The Neoproterozoic sedimentary rocks include the Vaughan Springs Quartzite, the Mt. Doreen Formation and the Yuendumu Sandstone. These are overlain by the Cambrian Walbiri Dolomite and the Bloodwood Formation followed by the Ordovician Djagamara Formation and Kerridy Sandstone and the Carboniferous Mt. Eclipse Sandstone. Cainozoic sediments unconformably overlie the basin sequence and in the central part of the basin these can be in excess of 250m thick.

3.1 Structure

The Ngalia basin was moderately deformed by Neoproterozoic and Carboniferous orogenies. Neoproterozoic tectonism resulted in major faulting and minor folding along the north margin of the basin. A Carboniferous orogeny caused major faulting, thrusting and folding, with older basement being thrust over basin sediments in places along the Yuendumu Thrust.

Basement lithologies are dominated by west northwest trending faults. Ngalia Basin sediments are folded into broad to open folds with fold axes striking east west. The most prominent structural feature within the tenement is the Yuendumu Thrust fault.

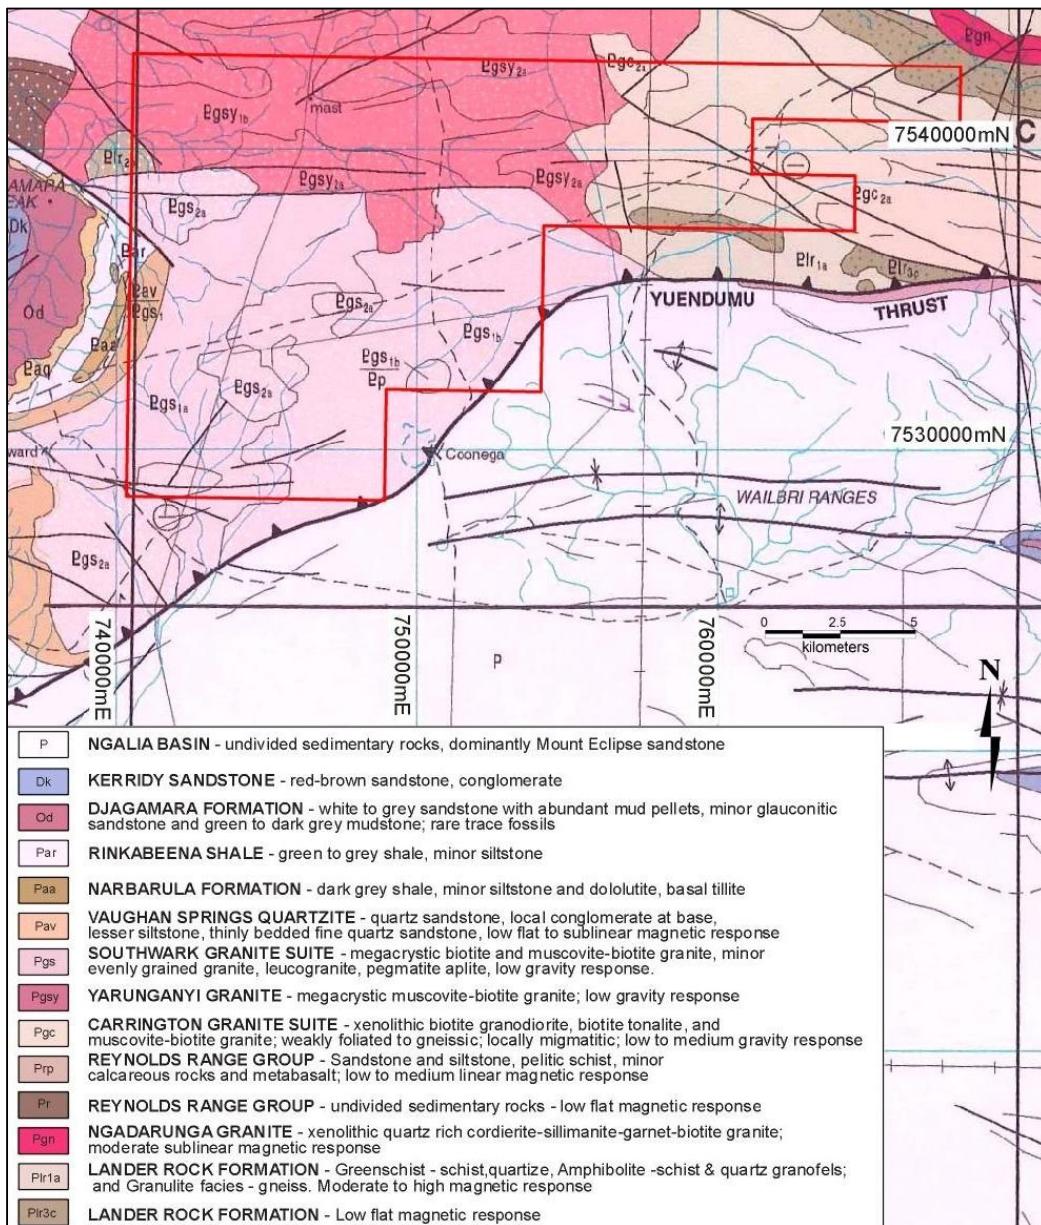

Figure 2. Interpreted geology of EL 24566.

3.2 Mineralisation

The Ngalia Basin was the centre of active uranium exploration during the 1970s and early 1980s, with the focus on roll front uranium mineralisation hosted within the Devonian to Carboniferous aged Mount Eclipse Sandstone as well as for carnotite mineralisation hosted within recent surficial and near surface calcrete horizons. A number of significant uranium occurrences are located within the basin including the modified roll front style Bigrlyi Uranium deposit covering a strike length of 12 km containing an indicated resource of 4,190t U₃O₈ at a 500ppm cut-off. This deposit was identified in 1973 during basin wide exploration undertaken by Central Pacific Minerals NL and is now held by Energy Metals Limited (53%).

EL24566 is considered favourable for uranium exploration due to the numerous known uranium occurrences in the Ngalia Basin region and the regional geological setting. Specifically, “old” basement hosting an intracratonic basin. This geological environment has potential to host various uranium mineralisation styles including vein and fault hosted mineralisation, unconformity style of mineralisation and sandstone “roll front” style of mineralisation.

4. Mineral Exploration Activities

4.1 Drilling

In December 2008, UXA completed a drilling program over the Crystal Creek Anomaly A prospect. The program was designed to test for near surface uranium mineralisation and comprised 9 HQ diamond holes for a total of 1014m (Table 1, Figure 5), with 374 half core samples collected at varying intervals for assay. Graphic logs for all holes can be found in Appendix 1.

Hole	Easting	Northing	Azimuth	Dip	Total depth (m)	PFN/Gamma
08CC06	744546	7539712	347°	60°	273	Yes
08CC07	744546	7539712	0°	90°	57	Yes
08CC08	744780	7539870	0°	90°	51	Yes
08CC09	745027	7539756	0°	90°	72	Yes
08SC10	745015	7539503	0°	90°	108	Yes
08SC11	744781	7539322	0°	90°	117	Yes
08SC12	744541	7539144	0°	90°	123	No
08SC13	744286	7538993	0°	90°	117	Yes
08SC14	744042	7538855	0°	90°	96	No

Table 1. 2008 drilling program details (GDA94, Zone 52).

All samples (Appendix 2) were assayed for Ag, As, Au, Ba, Co, Cu, Mn, Mo, Nb, Ni, Pb, Rb, Sn, Sr, Th, U, V, W, Y, Zn and Zr. Eighteen samples were selected and assayed for major oxides (Al_2O_3 , CaO, Fe_2O_3 t, K_2O , LOI, MgO, MnO, Na_2O , P_2O_5 SiO_2 , TiO_2), while ten samples were assayed for Rare Earth Elements (La, Ce, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, Yb, Lu) and F.

The main lithology encountered during drilling was megacrystic granite, which comprised large K-feldspar megacrysts, smaller plagioclase phenocrysts, quartz, biotite, chlorite and clay minerals. Rapakivi texture was also noted at various locations throughout the granite, with purple fluorite veins and rare fine grained pyrite occurring sporadically throughout the unaltered samples.

The drilling confirmed a vertical weathering/alteration profile within the granites. The top of the sequence was marked by almost complete kaolinisation of the granite, leaving only relict quartz crystals in a white to brown clay matrix with poor textural preservation (Figure 3a). This level of alteration persisted to an average depth of ~32m below surface. Below this was a moderately altered zone, in which K-feldspar was usually preserved but plagioclase was completely altered to clay (Figure 3b). Biotite was commonly altered to chlorite and textural preservation was moderate to poor. This moderate type of alteration persisted to an average depth of ~67m below surface. Largely unaltered “fresh” megacrystic granite was present below the moderately altered zone (Figure 3c).

Figure 3. Weathering/alteration profile documented from 2008 drilling;
(a) Heavily kaolinised, (b) moderately altered and (c) “fresh” granites.

The granite is overlain in several holes (08SC10, 08SC11, 08SC12, 08SC13 & 08SC14) by approximately 10m of a hard, quartz/clay rich unit which possibly represents the Vaughan Springs Quartzite. This in turn is usually capped by a thin (~1m) layer of hard, grey silcrete. The silcrete/quartzite sequence forms a mesa ~8 to 10m high above the surrounding flats, which are dominated by heavily kaolinised granite.

Uranium assay results were disappointing, with the best result being 1m @ 176ppm U (08CC07, 30-31m) from an alteration halo around a highly altered dolerite dyke. Concentrations of trace elements from the heavily and moderately altered zones were normalised against average values derived from the fresh granite samples to determine the level of element mobility throughout the weathering profile. Results varied for different elements (Table 2), with thorium remaining essentially immobile while uranium displayed only slight enrichment in the heavily altered zone (Figure 4).

The lack of uranium accumulation in the upper heavily kaolinised zones is reflected by the typically low response in the U²/Th radiometrics for the Anomaly A region (see Figure 5).

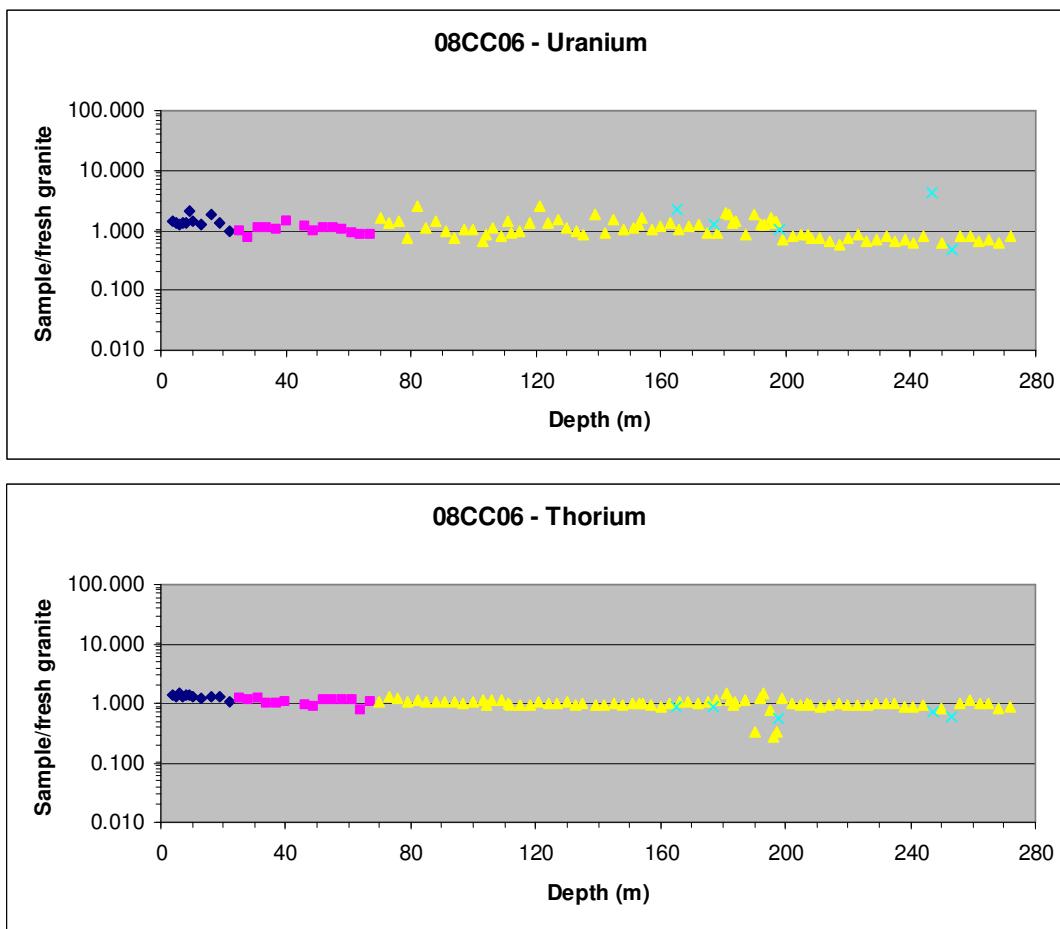

Figure 4. U and Th concentrations for heavily altered (blue), moderately altered (purple) and “fresh” granites (yellow) from drill hole 08CC06. Element concentrations have been normalised using average values from “fresh” granites to illustrate element mobility.

Element	Mod. Altered granite	Heavily altered granite
Co	Moderate depletion	Heavy depletion
Cu	Slight depletion	Slight enrichment
Mn	Moderate depletion	Heavy depletion
Ni	Slight depletion	Slight depletion
Th	No significant change	No significant change
U	No significant change	Slight enrichment
V	Slight depletion	Slight enrichment
Zn	Slight depletion	Mod - heavy depletion

Table 2. Element mobility trends through weathering/alteration profile of drill hole 08CC06.

Downhole logging of 7 drill holes (Table 1, Appendix 1) was carried out using a PFN and Gamma tool. Due to the low concentrations of uranium encountered during drilling (average 15ppm U & 58ppm Th from assays), the PFN tool was working below its detection limit and therefore the resulting data was not considered to be relevant. The Gamma tool data however typically corresponded well to observed geology, assay results and hand held scintillometer readings and was considered to be the most useful down-hole method for such low uranium concentrations.

4.2 Field mapping & sampling

Several field mapping trips were conducted to EL 24566 during the reporting period. The aim of the field mapping was to better define the surface geology and structural characteristics and also to map out any changes in the granites (textural, compositional, chemical, structural etc). During the current reporting period, a total of 38 rock chip samples have been submitted for comprehensive geochemical assay (Figure 5, Table 3, Appendix 3).

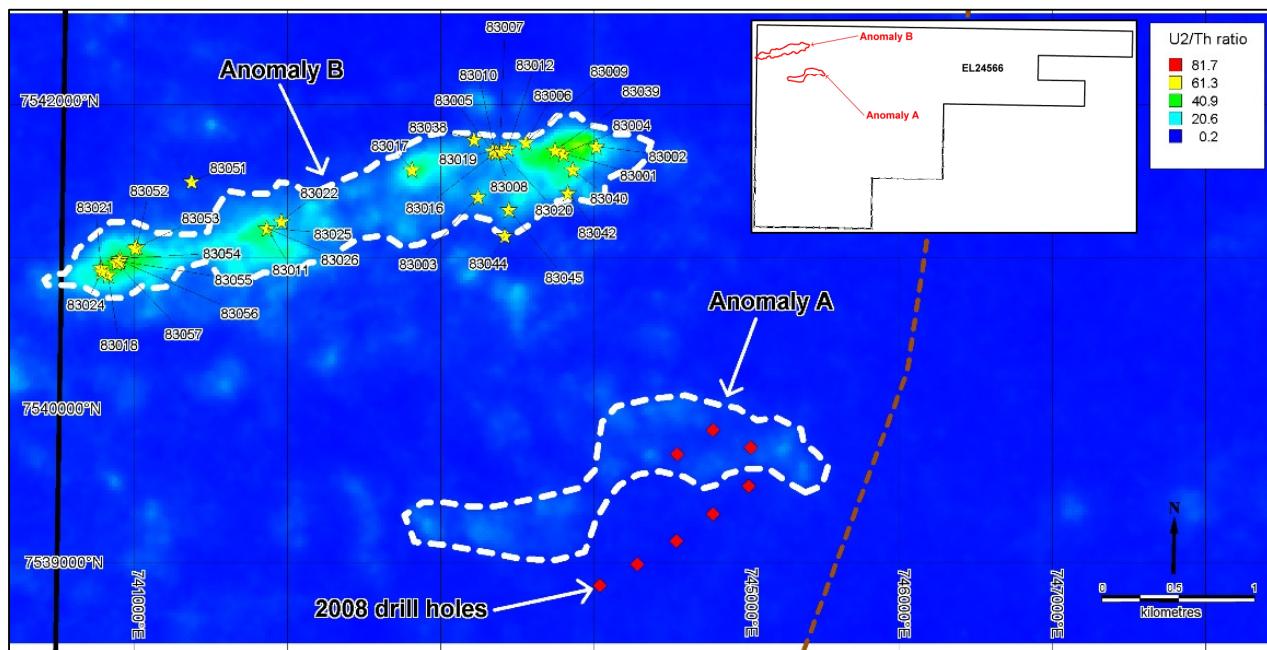

Figure 5. Sample locations around the Anomaly B region.

Geological mapping across the western half of the tenement suggests that the Southwark Granites within EL 24566 contain a number of compositional and textural variations including:

- Quartz-feldspar porphyry. Fine grained groundmass containing sporadic, often rounded quartz phenocrysts (up to 1cm diameter) and large, sporadic feldspar phenocrysts/megacrysts in a groundmass comprising mostly quartz, feldspar & mica. Field evidence suggests that varying degrees of greisenisation may have occurred, particularly in the Anomaly B region. Miarolitic texture is common in this rock type (Figure 6a).

Uranium Exploration Australia Limited
Ngalia Thrust - Annual Report 21 October 2008 to 20 October 2009

- Megacrystic granite. Large K-spar megacrysts (up to 12cm diameter), plagioclase phenocrysts, quartz, biotite, chlorite. Rapakivi texture may be present also (Figure 6b).
- Coarse, equigranular granite. Typically lacks megacrysts, with a relatively uniform coarse (2-5cm) grainsize. Can tend to be more friable, with mineralogy similar to megacrystic type (Figure 6c).
- Late stage felsic dykes. Typically fine grained, occur as dykes within megacrystic granites (Figure 6d).

Sample ID	Easting	Northing	Description	Scintillometer (cps)	U (ppm)	Th (ppm)
83001	743801	7541681	Qtz-fsp porphyry	1100	80	15

Table 3. Details of field samples assayed during the reporting period.

The Anomaly B region comprises predominantly miarolitic, fine grained quartz-feldspar porphyry and coarse, equigranular granite rock types (Figure 6). The porphyritic rocks tend to provide the highest scintillometer readings, with areas of greisenisation also apparent in the region. Conjugate shear sets trending $\sim 250^\circ$ and 290° are evident in outcrop throughout the area.

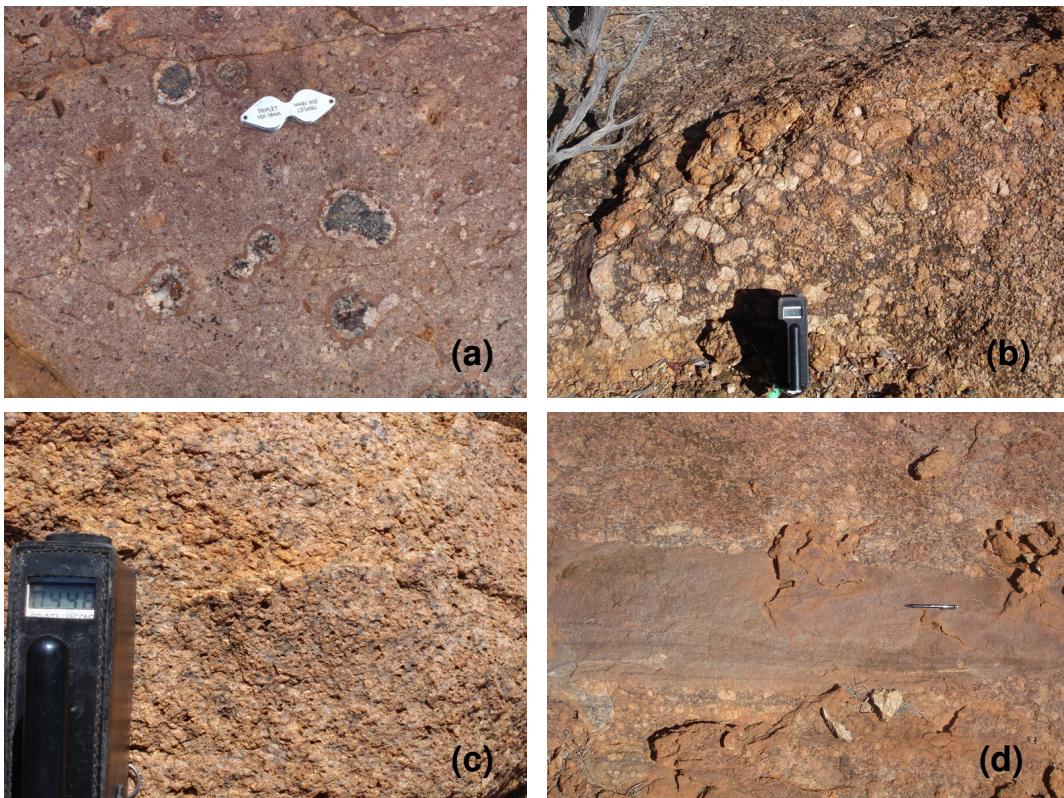

Figure 6. Textural variations within granites from EL 24566 including; (a) Fine grained quartz-feldspar porphyry with miarolitic texture, (b) megacrystic granite, (c) coarse equigranular granite and (d) fine grained felsic dyke.

Granites that display a wide textural variation are interpreted as being emplaced at shallow levels in the crust, with porphyritic textures commonly reported in ore associated granites (Candela, 1997). The miarolitic cavities, which are relatively common throughout Anomaly B within the fine grained porphyry, also suggest that the magma in this region was saturated with respect to volatile phases.

Moving north and south of Anomaly B, the rock type becomes predominantly megacrystic granite (variably kaolinised), with sporadic occurrences of the porphyry and equigranular granite rock types. Several occurrences of fine grained felsic dykes (late stage) have been documented to date within the megacrystic granites peripheral to the Anomaly B region. These dykes commonly have a distinctively high scintillometer reading compared to the encompassing megacrystic granites, with assays reporting elevated levels of either uranium or thorium (eg samples 83015 & 83045).

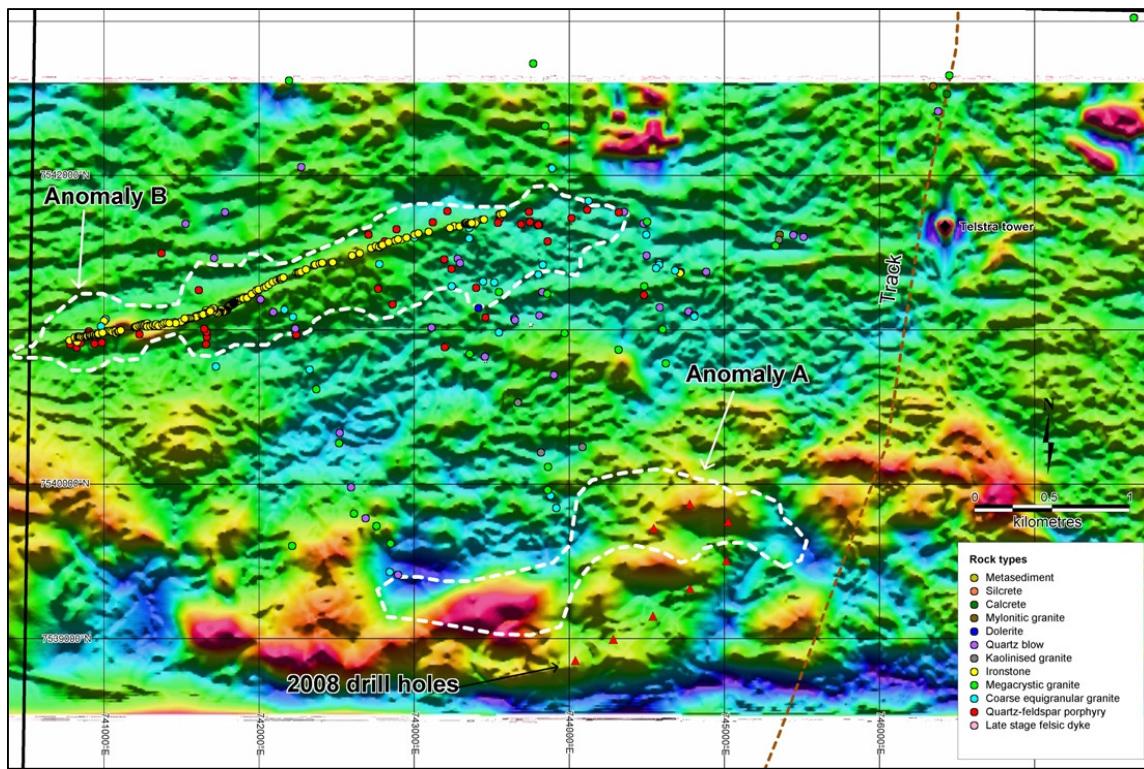

Figure 7. Mapping points and documented rock types in the Crystal Creek region. Background is RTP-HVD detailed magnetics from the 2009 survey.

A heavily weathered/alterred subcropping rock, suspected to be a dolerite, was also documented in the Anomaly B region (sample 83044). A mafic origin for this rock is supported by assay results, which indicate the rock contains elevated levels of Cr, Ni, Cu, V and Zn, with an MgO of 3.1 wt%. This occurrence is coincident with a significant ~east-west trending structure immediately south of Anomaly B (Figure 7), and could indicate that this structure is indeed a dolerite dyke largely concealed by cover. Dolerite dykes reported within the MOUNT DOREEN 1:250,000 map sheet are thought to be Neoproterozoic in age (around 1060 Ma, Young et al, 1995) and therefore postdate the Southwark Granite Suite.

The ironstone lode mapped within Anomaly B is approximately 3km in strike length and comprises massive ironstone/quartz outcrop/subcrop, with an average width of ~2m along strike. It is hosted predominantly by the quartz-feldspar porphyry rock type and has a strike trending ~250°. Concentrations of Fe₂O₃ (hematite) from the ironstone samples vary from 6.8 to 38.9 wt%, with elevated levels of Co, Cr, Ni, TiO₂, U, V and Zn also reported (Appendix 3). The best uranium results included 4000ppm and 3600ppm from samples 83006 and 83009 respectively, although uranium results tend to be patchy along strike.

QEMSCAN analysis was carried out on ironstone samples 83006 and 83009 to help determine the uranium phase present (Appendix 4). Results of this work suggested that up to 5% of uranium was hosted by Ti-Fe oxides, while up to 30% of uranium could be hosted by REE phases (such as Xenotime, Monazite etc) which were considered to be relatively abundant.

Subsequent further assays revealed that even though the ironstones do contain elevated REE element levels (relative to the felsic rocks throughout EL 24566), the overall concentrations of the REE's are too low to be considered economically relevant (Table 4). Due to the presence of complex mineral textures and intergrowths, the results of the QEMSCAN work were considered largely inconclusive. At the time of reporting, samples 83006 and 83009 had been submitted to the University of Adelaide for detailed SEM/microprobe analysis. Results are pending.

4.3 Soil geochemical survey

A soil sampling survey was conducted over the Anomaly B region during September 2009. The survey comprised 20 lines at 200m spacings, with samples taken every 20 metres for a total of 599 samples. At each sample point, the top 3cm of material was cleared and approximately 1.5kg of soil taken, with the coarse fraction removed from the final sample by sieve. The samples were then analysed for a suite of elements via ICP-OES and ICP-MS including Cr, Cu, Ni, P, S, Ti, V, As, Ce, Co, La, Nb, Pb, Sm, Sb, Sn, Ta, Th, U, Y, Zn and Zr (Appendix 5).

Results from this survey indicate that the ironstone lode can be mapped out successfully using elevated Co, Cr & Ni readings (and to a lesser extent Ti & V, Figure 8). This is supported by rock chip assay results, which show that the ironstone contains elevated levels of these elements with respect to other rock types in the region.

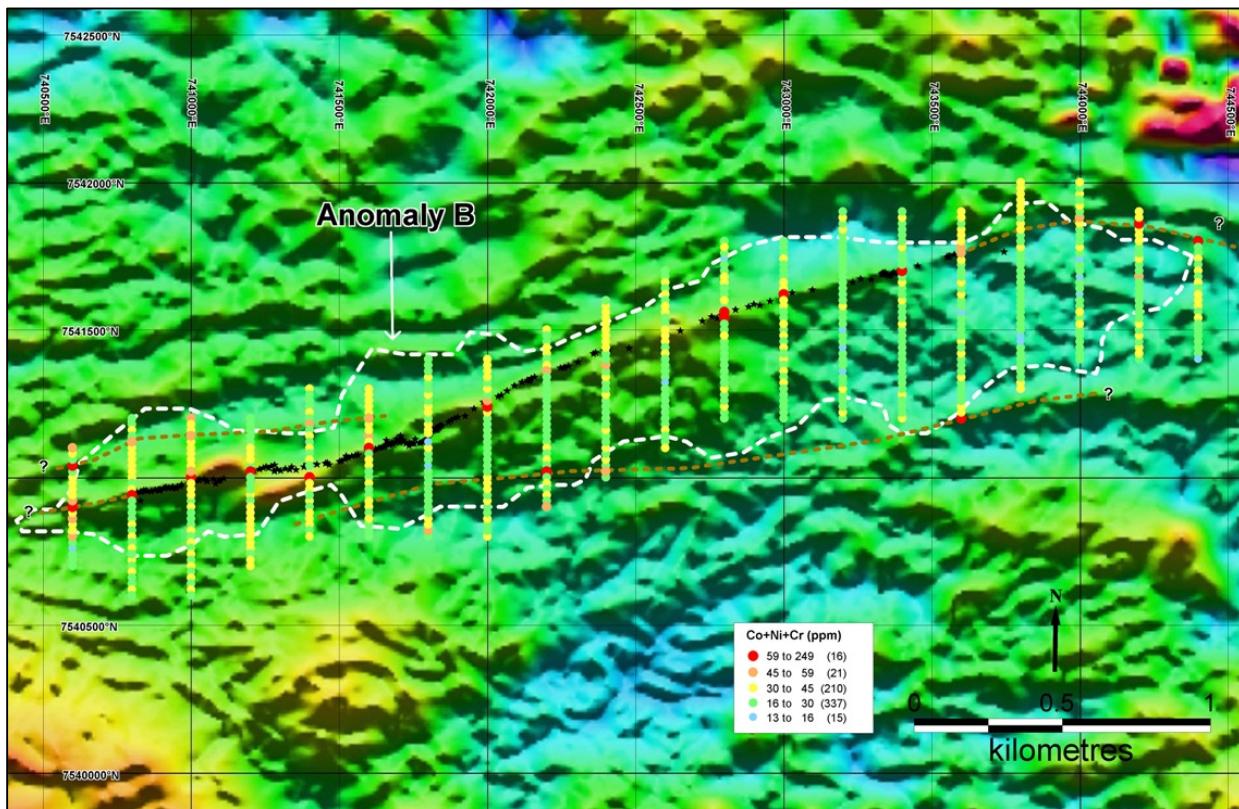

Figure 8. Cr+Co+Ni plot over magnetics (RTP, HVD) from soil geochemical survey. Black stars indicate position of outcropping ironstone lode, brown dashed lines indicate possible extensions/concealed structures.

The survey results also suggest that tantalum and niobium correlate well with areas of elevated U^2/Th ratio from the detailed radiometrics (Figure 9), suggesting that these elements may be useful pathfinders for the quartz-feldspar porphyry rock type under cover. Both Ta and Nb behave as incompatible, High Field Strength Elements (HFSE) during crustal processes and are considered to be immobile during hydrothermal processes. Therefore the correlation of these elements with the rock types (and U^2/Th radiometrics) at Anomaly B could suggest they are the result of primary igneous processes (i.e concentrating in late stage melts, accessory minerals, volatile phases) rather than a product of secondary alteration.

The best uranium result was 29ppm U, with a median of 9.5ppm U across the 599 samples. The areas of elevated uranium generally correlate well with the U^2/Th radiometrics, although there is an area of elevated uranium outside the main elevated U^2/Th regions in the northeastern portion of Anomaly B (Figure 10). This area of elevated uranium also corresponds with elevated Sn and Pb results (and to a lesser extent La & Ce). These anomalies could be the result of localised mineralisation or an analytical batch error. Selected samples from the soil survey have been resubmitted to a second laboratory as a QA/QC measure to ensure these anomalies are real, with results pending.

4.4 Geophysics

In September 2009, UTS Geophysics was commissioned by UXA to perform a high resolution airborne radiometric and magnetic survey over the northwest corner of EL 24566 (Figure 12, Appendix 5). The survey comprised a total of 1,913 line km's at 25m line spacings, with a sensor height of 20m. It was designed to provide high resolution data over the entire Crystal Creek prospect to help identify any further ironstone structures concealed beneath cover.

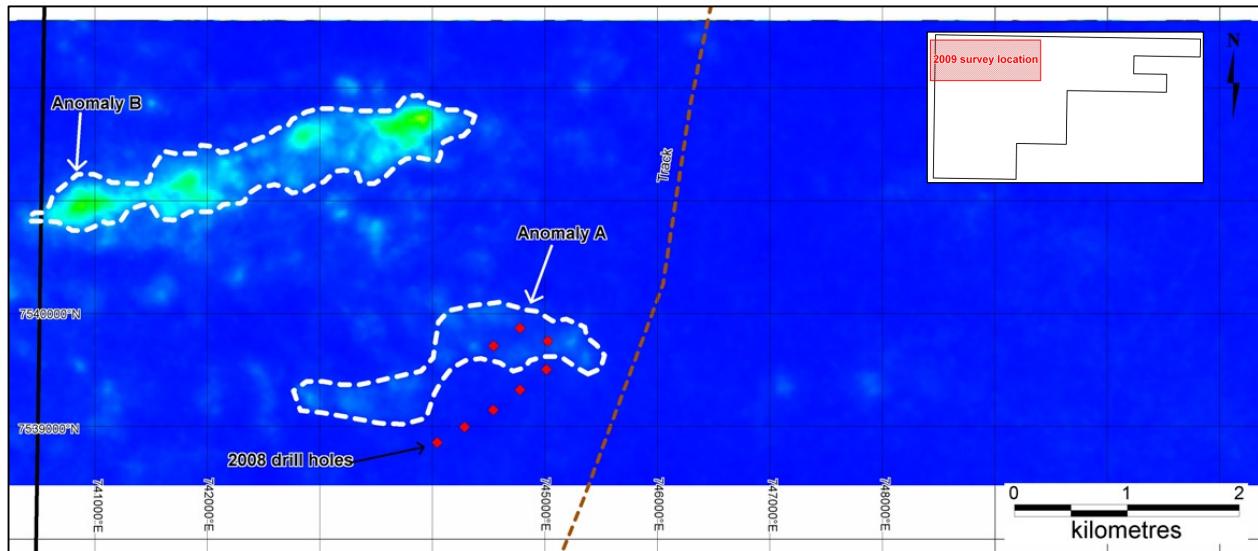

Figure 12. High resolution U^2/Th image over the Crystal Creek prospect.

The detailed magnetic data (Figure 13) suggests a possible second ironstone structure (predominantly undercover) trending approximately east-west immediately south of Anomaly B.

Furthermore, two standalone magnetic features (Target 1 & 2) may also be of interest as they appear to sit at junction points of regional conjugate shear sets. These targets may represent further ironstone bodies (albeit richer in magnetite than the oxidised ironstone lode at Anomaly B) and are considered highly prospective for hosting mineralisation.

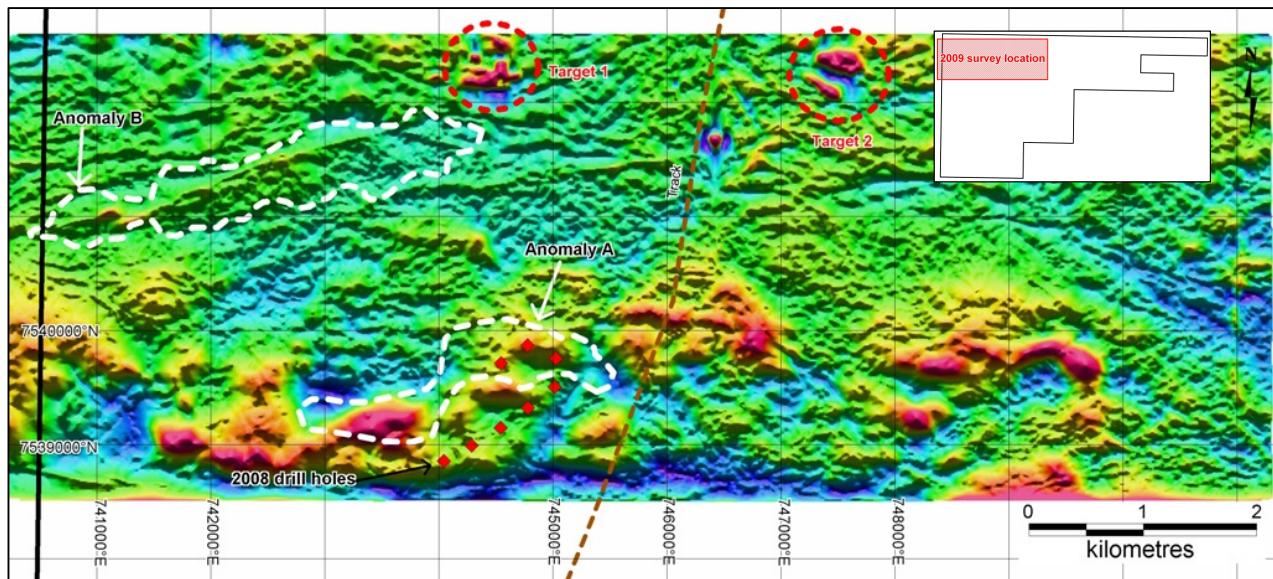

Figure 13. Detailed magnetics over Crystal Creek Prospect. Reduced To Pole (RTP) & Half Vertical Derivative (HVD).

5. Expenditure Statement

Exploration expenditure for the period 21 October 2008 to 20 October 2009 amounted to \$904,161.82. A detailed breakdown of expenditure is given in Appendix 6.

6. Conclusion and Recommendation

At the time of reporting, UXA is in the final stages of preparation for a drilling program, expected to commence mid-November. The program will comprise ~2,500m of RC drilling and will be focused primarily on the uraniferous ironstone lode in the Anomaly B region. There is also scope to test the potential second ironstone structure immediately south of Anomaly B, and also Target 1 further to the north during this program. UXA believes there is excellent potential to discover further mineralisation beneath Cainozoic cover throughout EL 24566.

Hole ID: 08CC06

Tenement: EL 24566 Ngalla Thrust

Easting: 744546

Northing: 7539712

Datum: WGS84 Z52

Drill hole details:

Includes drill hole name and location coordinates.

Grainsize:

- 1 = Very fine grained.
- 2 = Fine grained.
- 3 = Medium grained.
- 4 = Coarse grained.
- 5 = Very coarse grained.

PFN tool:

Prompt Fission Neutron tool, down-hole logging. Values are direct measurement of U₃O₈ (ppm).

Gamma tool:

Downhole gamma logging tool, measures gamma radiation. Scale represents parts per million (ppm)..

Scinto:

Hand-held Scintillometer passed over drill core. Measures gamma radiation in Counts Per Second (cps).

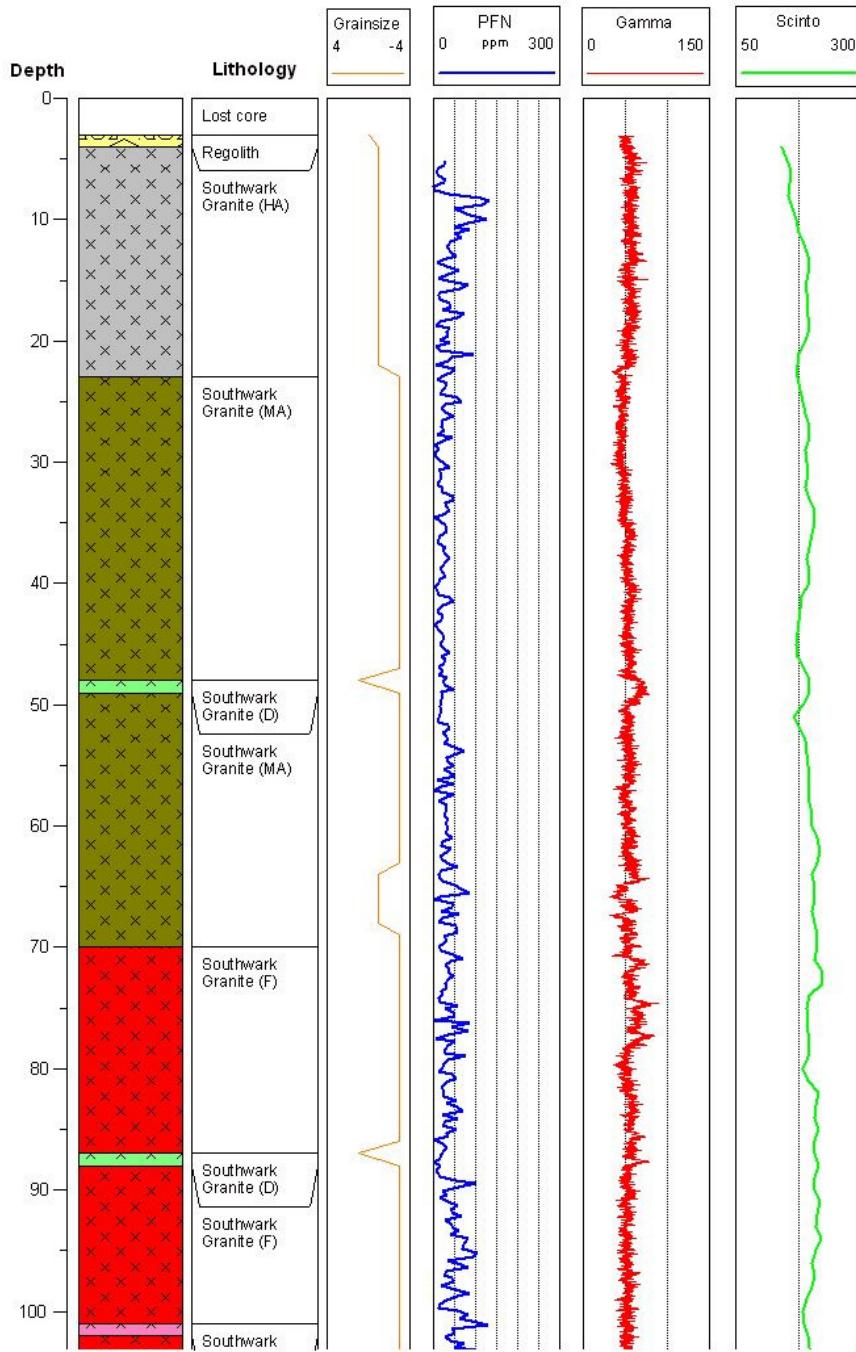

Rock types:

- Regolith = Surface soil/gravel horizon.
- Silcrete = Sand ± conglomerate cemented by secondary silica.
- Vaughan Springs Quartzite = Quartz-rich sediment unconformably overlying granite.
- Southwark Granite (HA) = Heavily clay altered granite. No primary textures preserved.
- Southwark Granite (MA) = Moderately clay altered, some primary textures preserved.
- Southwark Granite (F) = Fresh, mostly unaltered granite. Excellent textural preservation.
- Southwark Granite (PA) = Potassic? Alteration zones, usually associated with quartz veins.
- Southwark Granite (D) = Late stage aplite dyke within megacrystic granite.

Appendix 2 - 2008 drilling geochemistry

Genalysis Laboratory Services Pty Ltd analytical sample preparation and techniques

The Preparation of Mineral Exploration Samples

The standard sample preparation procedure at Genalysis is:

Single Stage Mix and Grind (SSMG) (limited to samples not exceeding 3kg)

General Description

Dry total sample, (jaw crush if necessary); single stage mix and grind total sample in an appropriately sized pulveriser (ring mill or puck type). Optional barren quartz clean of bowl between samples. Approximately 200g (or more, depending on the analytical requirements) is packaged in a paper sample envelope as the laboratory portion. The balance of the bulk pulp is stored in a new plastic bag.

Pulveriser bowls of “removable” configuration are available in 50g, 100g, 300g and 750g capacities. The typical maximum capacity of “fixed” configuration is 3kg.

Samples up to 750g

For samples up to 750g, the grinding efficiencies are such that particle size of the product is not normally an issue. Grinding times are relatively short (1 to 2 minutes).

Samples greater than 750g up to 3kg

For the 3kg capacity mills the grinding time is set at four minutes. Test work has shown that particle size distribution may not be improved by grinding for longer than four minutes. Whilst the aim is to produce a bulk pulp of nominally 90% minus 75 micron, this may not be achievable with certain very hard samples. If fine grind is considered essential, please discuss sample preparation options with Genalysis management prior to commencement of any project.

Disc Mills

Genalysis does **not** use disc mills either vertically mounted (Braun and Bico) or horizontally mounted (Keegor).

AT/OES and AT/MS

Multi-acid attack including hydrofluoric, nitric, perchloric and hydrochloric acids in teflon tubes. Suitable for dissolving silica based samples requiring low levels of detection. This digest approaches total dissolution for most minerals. Some minor chromium and antimony losses may occur. Elements incorporated in highly resistant minerals may not be dissolved; these include, but are not limited to, zircon, rutile, ilmenite, tantalite, columbite, cassiterite, wolframite, spinels and some garnet species.

0.2 g pulped sample is digested with a mixture of HNO₃, HClO₄ and HF in teflon tubes placed in a Hot Box. The temperature and duration of the digest are electronically controlled starting from 25 DegC to 240 DegC. At the end of the 16-hour digest the samples are cooled and then leached with HCl and finally made up to a volume of 20 ml with doubly deionised water.

This final solution is introduced to the ICPOES or ICPMS for analysis.

Fus/XRF

XRF is the preferred technique for determination of the major element oxides as well as some trace elements, particularly those with solubility issues. Two principal sample pretreatment techniques are used; pressed powder and fused disc. Pressed powders are generally used for determining trace elements but these analyses may be subject to particle size and matrix effects which increase analytical uncertainty, particularly in the light elements. Fusion techniques reduce the matrix effects and eliminate particle size effects; providing more precise major element data, however dilution makes this generally less suitable for trace elements.

0.7g of the pulped sample is mixed with a suitable flux (usually lithium borate mixtures) and fused at ~1000 degC. The exact ratio of sample to flux can be altered to suit the samples matrix. The product is poured into a mould to obtain a homogenous fused disc which is then presented to either a Pan Magix XRF (simultaneous instrument) or a Pan Axios (sequential instrument) for analysis. The analysis normally includes the determination of the loss on ignition (LOI) at a range of temperature up to 1000 degC, this result is included in the analysis to allow for full correction of the matrix.

TGA

Thermo gravimetric LOI analyses at up to four different temperatures. Approximately 1gram portion of the sample is heated at a range of temperatures starting at 105degC normally through to 1000 degC. The sample is repeatedly weighed until a constant mass is obtained at each temperature and then the loss in mass is calculated.

FUSION DH/SIE

Carbonate fusion in nickel crucible specific for fluoride, determined by SIE.

B/SAAS

Aqua regia will attack most rock types, however silicates and refractory minerals will remain largely un-dissolved. Aqua regia is a useful tool for exploration, however, it is not suitable for resource work.

DIGESTION B (10g charge)

The digested and leached sample is vacuum filtered and diluted to volume. Elements by solvent extraction and flame AAS (SAAS).

Appendix 3 - Rock chip assay results

Amdel Ltd analytical sample preparation and techniques

Sample preparation (PREP3,2)

For samples up to 3kg in weight, the samples will be dried to a core temperature of approximately 100°C. The total sample will be jaw crushed to a nominal 5mm particle size and then milled in a LM5 pulveriser to 90% passing 106um. An analytical pulp of 250g will be taken from the bulk and the residue retained, where practical, in the original bag.

XRF1

XRF analysis by pressed powder. XRF determines total values and is suitable for the analysis of drill core, rocks, stream sediments and soils.

IC3E

A subsample of 0.2g of the analytical pulp is digested using a HF/multi acid digest and the solution is presented to an ICPOES for the quantification of the elements of interest.

IC4

A 0.1g subsample of the analytical pulp is fused with lithium metaborate followed by dissolution to give a “total solution”. The solution is presented to an ICPOES for the determination of the elements of interest.

IC4M

A 0.1g subsample of the analytical pulp is fused with lithium metaborate followed by dissolution to give a “total solution”. The solution is presented to an ICPMS for the determination of the elements of interest.

IC4R

A 0.1g subsample of the analytical pulp is fused with lithium metaborate followed by dissolution to give a “total solution”. The solution is presented to an ICPMS for the determination of the elements of interest.

AA3

A subsample of 0.2g is digested in a mixture of hydrochloric acid, hydrofluoric acid, nitric acid and perchloric acid to effect dissolution of base metals. The resulting residue is bulked to volume with acid and quantified by AAS.

FA3E

A subsample of 40g of the analytical pulp is fused in a lead collection fire assay. The resulting prill is digested in aqua-regia and the gold content of the sample is determined by ICPOES.

Appendix 4 - QEMSCAN report summary

Modes of Analyses

BMA analysis

BMA is a linear method. Each block is scanned in the X direction, with the Y-direction line spacing being set such that each particle is intersected once. As the entire block is scanned, this produces an extremely high statistical population – with the random alignment of the particles ensuring appropriate sampling.

All information listed below is available from this mode of measurement. The new Intellection processing software, iExplorer, now enables liberation and locking information to be extrapolated from this form of analysis method.

- Modal Mineralogy
- Grain Size Estimation
- Elemental Deportment
- Mineral Associations
- Liberation (*area % only*)
- Locking (*area % only*)
- Size-by-size elemental & mineralogical reconciliation

This is a good analysis method for low grade species, as the intercept statistics are higher.

TMS and SMS analyses

TMS & SMS are particle analysis methods, which only analyse a pre-set subpopulation of the particles present. They are based on the premise that the phases of primary interest (ie target phases) have a higher back-scattered electron brightness than the bulk of the gangue phases.

This enables each block to be scanned for particles containing the target phase(s), and only those of interest are fully analysed. As the entire block is scanned, this also produces the highest possible statistical population for the trace phase.

All information listed below is available from this mode of measurement, but relates only to the subpopulation analysed. This is a particularly good analysis method for determining losses of sulphides and precious metal phases to silicate-rich tails.

- _ Modal Mineralogy
- _ Grain Size Estimation
- _ Elemental Deportment
- _ Mineral Associations
- _ Liberation (*area % and surface area %*)
- _ Size-by-size elemental & mineralogical reconciliation

SMS and TMS differ, only on the basis of bright-phase content. E.g. if bright phases are ~ >1%, SMS is applied, if bright phases are ~<1%, TMS is used.

Recommended for good statistics on the trace phases.

Field Scan analysis

The Field Scan (FS) mode of measurement maps a rock chip or core sample that has been mounted in the polished section. It collects a chemical spectrum at a set interval within the field of view. Each field of view is then processed offline to generate a single integrated image and a false-colour image of the core sample is produced.

EXECUTIVE SUMMARY

Seven rock samples with elevated scintillometer readings were submitted to the SGS Advanced Mineralogy Facility in Brisbane for mineralogical investigation. The client was particularly interested in information on the uranium-bearing minerals in the samples.

It should be noted that, in most cases, only a single fragment, with a maximum dimension of about 30mm, was selected for mineralogical investigation. This fragment is unlikely to be representative of the entire sample and it is recommended that any further mineralogical work be carried out on a larger number of fragments.

The results show that the two porphyry samples (83003 and 83004) are mainly composed of quartz, feldspars and sericite. The four ironstone samples (83006 to 83009) are composed of variable proportions of quartz, sericite, chlorite and iron and/or titanium oxides. The dominant minerals in the altered granite sample (83023) are quartz, K-feldspar and kaolinite.

Although high resolution analyses were carried out on the samples, no classical, discreet, uranium-rich minerals (such as uraninite, autunite and coffinite) larger than a few micrometres were detected. Of these discrete uranium minerals, brannerite, apparently with a relatively high iron content, is the most common.

Trace amounts of REE-bearing minerals were detected in all of the samples. Semi-quantitative analyses of a large number of points on these REE minerals show that some contain uranium at levels ranging between 1 and 30 mass percent. It appears that titanium-iron-oxide phases associated with the REE-bearing phases may also have uranium contents of up to 5 mass percent.

Most of the uranium-bearing minerals that were detected in the samples have complicated chemistries and display very complex textural relationships with the associated minerals such as clays and micas. The presence of these complex intergrowths makes unambiguous identification of the minerals and their uranium contents very difficult.

Due to the complex mineralogy and textures of the uranium-bearing minerals, it is not possible to provide quantitative uranium deportment data. However, it is possible that the titanium-iron-oxide type minerals host the bulk of the uranium with most of the balance hosted by the uranium-bearing REE minerals. Detailed microprobe work will need to be done to confirm the observation made during this investigation.

Appendix 5 - Soil geochemical survey results

Amdel Ltd analytical sample preparation and techniques

Sample preparation (PREP2)

For samples up to 3kg in weight, the samples will be dried to a core temperature of approximately 100°C. The total will then be milled in a LM5 pulveriser to 90% passing 106um. An analytical pulp of 250g will be taken from the bulk and the residue retained, where practical, in the original bag.

IC3E

A subsample of 0.2g of the analytical pulp is digested using a HF/multi acid digest and the solution is presented to an ICPOES for the quantification of the elements of interest.

IC3M

A subsample of 0.2g of the analytical pulp is digested using a HF/multi acid digest and the solution is presented to an ICPMS for the quantification of the elements of interest.

Appendix 6 – Airborne radiometric & magnetic survey specifications

3 AIRCRAFT AND SURVEY EQUIPMENT

The UTS navigation flight control computer, data acquisition system and geophysical sensors were installed into a specialised geophysical survey aircraft.

The list of geophysical and navigation equipment used for the survey is as follows:

General Survey Equipment

- FU24 – 954 fixed wing survey aircraft.
- UTS proprietary flight planning and survey navigation system.
- UTS proprietary high speed digital data acquisition system.
- Novatel, 12 channel precision navigation GPS.
- OMNISTAR real time differential GPS system.
- UTS LCD pilot navigation display and external track guidance display.
- UTS post mission data verification and processing system.
- Bendix/King KRA-405 radar altimeter.

Magnetic Data Acquisition Equipment

- UTS tail stinger magnetometer installation.
- Cesium Vapour total field magnetometer.
- Fluxgate three component vector magnetometer.
- RMS Aeromagnetic Automatic Digital Compensator (AADC II).
- Diurnal monitoring magnetometer (Scintrex Envimag or Geometrics GR-856).

Radiometric Data Acquisition Equipment

- Exploranium GR-820 gamma ray spectrometer.
- Exploranium gamma ray detectors.
- Barometric altimeter (height and pressure measurements).
- Temperature and humidity sensor.

UTS Geophysics Logistics Report
Page 5

3.1 Survey Aircraft

The aircraft used for this survey was a FU24-950 series fixed wing survey aircraft, owned and operated by UTS Geophysics, registration VH-HVP.

The specifications are as follows:

Power Plant

- Engine Type Single engine, Lycoming, IO-720
- Brake Horse Power 400 bhp
- Fuel Type AV-GAS

Performance

- Cruise speed 105 Kn
- Survey speed 100 Kn
- Stall speed 45 Kn
- Range 970 Km
- Endurance (no reserves) 5.6 hours
- Fuel tank capacity 490 litres

3.2 Data Positioning and Flight Navigation

Survey data positioning and flight line navigation was derived using realtime differential GPS (Global Positioning System).

Navigation was performed using a UTS designed and built electronic pilot navigation system providing computer controlled digital navigation instrumentation mounted in the cockpit as well as an externally mounted track guidance system.

GPS derived positions were used to provide both aircraft navigation and survey data location information.

The GPS systems used for the survey were:

- Aircraft GPS Model Novatel
- Sample rate 0.5 Seconds (2 Hz)
- GPS satellite tracking channels 12 parallel
- Typical differentially corrected accuracy 1-2 metres (horizontal)
3-5 metres (vertical)

UTS Geophysics Logistics Report
Page 6

3.3 UTS Data Acquisition System and Digital Recording

All geophysical sensor data and positional information measured during the survey was recorded using a UTS developed, high speed, precision data acquisition system. Survey data was downloaded onto magnetic tape on completion of each survey flight.

Instrument synchronisation times were measured and removed in realtime by the UTS data acquisition system.

3.4 Altitude Readings

Accurate survey heights above the terrain were measured using a King radar altimeter installed in the aircraft. The height of each survey data point was measured by the radar altimeter and stored by the UTS data acquisition system.

- Radar altimeter models Bendix/King KRA-405
- Accuracy 0.3 metres
- Resolution 0.1 metres
- Range 0 - 762 metres
- Sample rate 0.1 Seconds (10Hz)

The digital terrain model is calculated by subtracting the terrain clearance

(radar altimeter) from the GPS height (interpolated to 0.1 Hz), and as such the accuracy is constrained by the differentially corrected GPS position.

3.5 UTS Stinger Mounted Magnetometer System

The installation platform used for the acquisition of magnetic data was a tail mounted stinger. This proprietary stinger system was constructed of carbon fibre and designed for maximum rigidity and stability.

Both the total field magnetometer and three component vector magnetometer were located within the tail stinger.

UTS Geophysics Logistics Report
Page 7

3.6 Total Field Magnetometer

Total field magnetic data readings for the survey were made using a Cesium Vapour Magnetometer. This precision sensor has the following specifications:

- Model Cesium Vapour Magnetometer
- Sample Rate 0.1 seconds (10Hz)
- Resolution 0.001nT
- Operating Range 15,000nT to 100,000nT

3.7 Three Component Vector Magnetometer

Three component vector magnetic data readings for the survey were made using a Fluxgate Magnetometer. This precision sensor has the following specifications:

- Model Fluxgate Magnetometer
- Sample Rate 0.1 seconds (10Hz)
- Resolution 0.1nT
- Operating Range -100,000nT to 100,000nT

3.8 Aircraft Magnetic Compensation

At the start of the survey, the system was calibrated for reduction of magnetic heading error. The heading and manoeuvre effects of the aircraft on the magnetic data was removed using an RMS Automatic Airborne Digital Compensator (AADC II).

Calibration of the aircraft heading effects were measured by flying a series of pitch, roll and yaw manoeuvres at high altitude while monitoring changes in the three axis magnetometer and the effect on total field readings. A 26 term model of the aircraft magnetic noise covering permanent, induced and eddy current fields was determined. These coefficients were then applied to the data collected during the survey in real-time.

UTS static compensation techniques were also employed to reduce the initial magnetic effects of the aircraft upon the survey data.

UTS Geophysics Logistics Report
Page 8

3.9 Diurnal Monitoring Magnetometer

A base station magnetometer was located in a low gradient area beyond the region of influence of any man made interference to monitor diurnal variations during the survey.

The specifications for the magnetometer used are as follows:

- Model Scintrex Envimag or Geometrics GR-856
- Resolution 0.1 nT
- Sample interval 5 seconds (0.2 Hz)
- Operating range 20,000nT to 90,000nT
- Temperature -20°C to +50°C

3.10 Barometric Altitude

An Air DB barometric altimeter was installed in the aircraft so as to record and monitor barometric height and pressure. The data was recorded at 0.10 second intervals and is used for the reduction of the radiometric data.

- Model Air DB barometric altimeter
- Accuracy 2 metres
- Height resolution 0.1 metres
- Height range 0 - 3500 metres
- Maximum operating pressure: 1,300 mb
- Pressure resolution: 0.01 mb
- Sample rate 10 Hz

UTS Geophysics Logistics Report
Page 9

3.11 Temperature and Humidity

Temperature and humidity measurements were made during the survey at a sample rate of 10Hz. Ambient temperature was measured with a resolution of 0.1 degree Celsius and ambient humidity to a resolution of 0.1 percent.

3.12 Radiometric Data Acquisition

The gamma ray spectrometer used for the survey was capable of recording 256 channels and was self stabilising in order to minimise spectral drift. The detectors used contain thallium activated sodium iodide crystals.

Thorium source measurements were made each survey day to monitor system resolution and sensitivity. A calibration line was also flown at the start and end of each survey day to monitor ground moisture levels and system performance.

Spectrometer model Exploranium GR820

- Detector volume 32 litres
- Sample rate 1 Hz

Appendix 7 – Expenditure form

**NORTHERN TERRITORY EXPLORATION EXPENDITURE
FOR MINERAL TENEMENT**

Section 1. Tenement type, number and operation name: (One licence only per form even if combined reporting has been approved)

Type	Exploration Licence
Number	24566
Operation Name (optional)	Ngalia Thrust

Section 2. Period covered by this return:

Twelve-month period:		If Final Report:	
From	21/10/08	From	
To	20/10/09	To	
Covenant for the reporting period:			\$200,000

Section 3. Give title of accompanying technical report:

Title of Technical Report	Ngalia Thrust Annual Technical Report on EL 24566 for the period 21/10/2008 to 20/10/2009
Author	Jason Cherry

Section 4. Locality of operation:

Geological Province	Arunta Inlier
Geographic Location	1:250,000 map sheet – Mount Doreen; 1:100,000 map sheets – Doreen, Yuendumu

Section 5. Work program for the next twelve months:

Activities proposed (please mark with an "X"):	<input checked="" type="checkbox"/> Drilling and/or costeanning
<input type="checkbox"/> Literature review	<input checked="" type="checkbox"/> Airborne geophysics
<input checked="" type="checkbox"/> Geological mapping	<input type="checkbox"/> Ground geophysics
<input checked="" type="checkbox"/> Rock/soil/stream sediment sampling	<input type="checkbox"/> Other:
Estimated Cost:	\$450,000

Section 6. Summary of operations and expenditure:

Please include salaries, wages, consultants fees, field expenses, fuel and transport, administration and overheads under the appropriate headings below. Mark the work done for the appropriate subsections with an "X" or similar, except where indicated. Complete the right-hand columns to indicate the data supplied with the Technical Report.

Do not include the following as expenditure (if relevant, these may be

- | | | |
|--------------------------|------------------|----------------------------------|
| • Insurance | • Transfer costs | • Land Access Compensation |
| • Company Prospectus | • Title Search | • Meetings with Land Councils |

EXPENDITURE**Section 7. Comments on your exploration activities:**

During the reporting period, exploration activities comprised the following:

- 9 diamond drill holes at the Crystal Creek prospect for a total of 1014m.
- Subsequent assay of 374 core samples for trace, major and rare earth elements.
- Downhole logging of 7 out of 9 drill holes using Prompt Fission Neutron (PFN) and gamma tool.
- Field mapping and sampling, including comprehensive assay and preliminary metallurgical work on 38 rock chip samples.
- QEMSCAN analysis of selected field samples.
- A detailed airborne radiometrics/magnetics comprising 1,913 line kilometres.
- A soil sampling survey over Anomaly B for a total of 599 samples, which were subsequently assayed.

I certify that the information contained herein, is a true statement of the operations carried out and the monies expended on the above mentioned tenement during the period specified as required under the *Northern Territory Mining Act* and the Regulations thereunder.

I have attached the Technical Report
