1. SUMMARY

East Mereenie 10 log and well test data have been interpreted to assess the Lower Stairway reservoir in that area. Gas and liquids were recovered in drill stem and production tests and there is evidence of a gas/oil contact at about 715 m (2345 ft) subsea.

Reservoir porosity is poorer than that of the Pacootta reservoirs. Permeability also appears poorer, though well test interpretations are considered tentative.

On the basis of an arbitrary Stairway oil/water contact at 852 m (2795 ft) subsea and pay parameters from East Mereenie 10, a possible Lower Stairway oil resource of 4.3 million barrels in place is suggested.

2. INTRODUCTION AND REPORT SCOPE

East Mereenie 10, drilled in late 1982 as the sixth well of an appraisal programme of the Mereenie field, was positioned to test the easterly extent of the Pacoota P1 oil reservoir.

Although the Pacoota reservoirs were found to be water saturated, a drill stem test in the Lower Stairway Sandstone produced gas at a reported rate of 3.02 MMCF/D and a small quantity of liquid hydrocarbons. The well is completed in this zone.

Flow tests of the Stairway Sandstone in earlier wells produced gas at more modest rates of up to 0.44 MMCF/D.

The results suggested that a significant new reservoir had been discovered and, in August 1984, a series of well tests was performed.

East Mereenie 10 log and well test data have been interpreted to evaluate the reservoir. The possibility of a Lower Stairway oil accumulation is discussed.

3. RESERVOIR PRESSURE AND TEMPERATURE

Static gradient data recorded in East Mereenie 10 on 1 April, 1984 with a Hewlett Packard gauge indicated a pressure of 2113.51 psia at 1341.1 mKB and 2125.88 psia at 1402.1mKB (gradient 0.0619 psi/ft).

At an adopted datum of 1413 mKB (714.7 m subsea), initial Lower Stairway reservoir pressure is 2128.04 psia. In comparison with the Pacootta reservoirs (P3: 1899 psia at 746.8 m (2450 ft) subsea; P1: 1931 psia at 816.9 m (2680 ft) subsea) the reservoir is overpressured*.

A static survey on 10 August 1984 indicated a reservoir pressure of 2127.36 at the datum, but pressure was increasing during the survey.

Temperature data recorded during the static surveys on 1 April 1984 and 10 August 1984 indicate a reservoir temperature of 59.78°C (139.6°F) and 59.39°C (138.9°F) respectively at the datum.

An average reservoir temperature of 59.6°C (139.3°F) is adopted.

Temperatures recorded during logging runs and drill stem tests were somewhat lower while temperatures recorded during a static survey on 24 August 1984 appear anomalous.

*Based on a Lower Stairway oil/water contact at 852 m (2795 ft) subsea (see later), the reservoir pressure is higher by some 240 psia.

4. RESERVOIR FLUID PROPERTIES

No subsurface sample of reservoir fluid has been taken in East Mereenie 10 and samples were not taken during the August 1984 flow tests.

Separate compositional analysis was performed on gas and liquid recovered from the Lower Stairway reservoir during DST #1 in East Mereenie 10. Reservoir fluid composition may be determined by combining the gas and liquid analyses if production rates are known.

The liquid flow rate in DST #1 is known from the volume recovered from the drill string on reverse circulation (6.5 barrels). The gas flow rate was calculated at 3.02 MMCF/D using a pressure drop of 290 psi across a 0.5" positive choke assuming a gas gravity of 0.65. As subsequent gas analysis indicated a gravity of 0.724, the calculated flow rate should be adjusted to 2.86 MMCF/D. On this basis, the gas/oil ratio would be 31.34 MCF/bbl and the reservoir fluid composition would be as listed in column (1) of Table 1. Dewpoint pressure at the reservoir temperature is estimated to be 2077 psia using a published correlation (Nemeth and Kennedy).

However, since the flow rate calculation assumes single-phase dry gas flow and no separator was used to remove natural gas liquids, it is expected that the actual flow rate was significantly lower.

As discussed in Section 6, DST and flow test interpretations would yield the same value of reservoir flow capacity if the DST flow rate were in fact only 0.52 MMCF/D of total fluids (0.44 MMCF/D of gas). On this basis, the gas/oil ratio would be 4.82 MCF/bbl and the reservoir fluid composition would be as listed in column (2) of Table 1. Dewpoint pressure is estimated to be 2273 psia, significantly above the average reservoir pressure of 2128 psia.

Column (3) of Table 1 shows the composition of the richest gas/liquid mixture predicted to exist in a single vapour phase at reservoir conditions. This reservoir fluid composition corresponds to a gas/oil ratio of 26.74 MCF/bbl and a DST gas flow rate of 2.44 MMCF/D. This is plausible -if the gas flow rate was in fact less than this figure, a Stairway oil leg in close proximity to East Mereenie 10 would be indicated. Composition (3) is assumed in well test interpretation (Section 6).

Table 1 also shows average Stairway gas composition from early wells. The markedly different composition confirms that the gas accumulation in the East Mereenie 10 area is separate from that seen in early wells. The lack of data precludes any conclusion on the areal extent of the accumulation, though drilling difficulties in East Mereenie 6 suggest that it is not confined to the immediate area of East Mereenie 10.

Gas properties at the adopted average reservoir conditions are noted in the Appendix. If there is a gas/oil contact at the datum (see later), the average gas reservoir pressure would be somewhat lower.

5. EAST MERENIE 10 LOG INTERPRETATION

A very limited log suite comprising CDL-GR-CAL and DIL-GR was run through the Lower Stairway reservoir. Hole condition was good; oil-based drilling fluid had been used.

Log interpretation indicates 4.6 m of net pay with 5.6% porosity and 18.1% water saturation between 1402.1 and 1437.1 m and 4.0 m of net pay with 5.6% porosity and 15.8% water saturation between 1411.0 and 1437.1 m KB. Cut-off limits for determination of net pay are shown in the Appendix, a 4% porosity cut-off being most significant.

Sensitivity analysis for the wider interval indicates that a 4.5% porosity cut-off would reduce hydrocarbon capacity by 21% while a 5% cut-off would reduce capacity by 50%.

No core was taken which might confirm log-derived porosity estimates.

Reservoir porosity is poorer than that of the Pacoota reservoirs (typically 8-12%).

6. EAST MERENIE 10 WELL TEST INTERPRETATION

In all well test interpretations, the rigorous pseudo-pressure technique is used. Although the gas composition on which pseudo-pressures are based is considered uncertain (refer Section 4), it is not expected that this would significantly affect results.

Computer printouts detailing test interpretation parameters are appended. Only buildup data are analysed.

On 10 November 1982, an open hole drill stem test (DST #1) over part of the Lower Stairway reservoir (1411.1-1436.8 m or 4629.7-4714 ft KB) was performed.

6½ barrels of liquid hydrocarbons were recovered from the drill string on reverse circulation. The gas flow rate was estimated without liquid separation facilities at 3.02 MMCF/D.

As mentioned in Section 4, the gas flow rate should be adjusted to 2.86 MMCF/D to account for the measured gas gravity. The calculated reservoir fluid flow rate was 2.94 MMCF/D allowing for the liquid hydrocarbons produced (average molecular weight 121.7, gas equivalent 831.9 SCF/bbl).

Interpretation suggests good reservoir permeability (21 md) and significant wellbore damage (skin pressure drop 1205 psi). If the DST gas flow rate were 2.44 MMCF/D (Section 4), the estimated reservoir permeability would 18 md.

These preliminary results justified further well testing which was undertaken in August 1984.

The well was flowed initially for 72 h (18/64" choke) with a 72 h buildup. The gas flow rate from the test separator varied from 0.61 to 0.80 MMCF/D while 6140 litres (38.6 bbl) of liquids were recovered. This is taken to be equivalent to a gas flow of 0.80 MMCF/D (0.81 MMCF/D of reservoir fluid) for 65 h.

A second flow period of 8 h (10/64" choke) with gas flow ranging from 0.55 to 0.433 MMCF/D is taken to be equivalent to a 9.52 h flow at the final rate or 0.44 MMCF/D of reservoir fluid.

A 16 h buildup was followed by a third flow (8 h, 14/16" choke) and buildup (16 h) and a fourth flow (4 h, 18/64" choke) and buildup. Data from these tests are treated in a similar manner.

The second, third and fourth buildups are interpreted as multi-rate tests. In each case, there is evidence of fluid inversion in the well tubing. The second flow was marred by variations in flowing pressure which appear not adequately explained by choke freezing. Because of this, the low value of skin factor from this test is considered erroneous.

Table 2 summarises the well test interpretations which are considered in very good agreement. Reservoir flow capacity is 48.5 md ft, reservoir permeability is 3.2 md if net pay is taken to be 4.6 m, apparent wellbore damage is substantial (apparent skin effect $S' = 17.71$). Deduction of the non-Darcy contribution (estimated from a general correlation) gave a true skin effect of 17.56.

A major difference between interpretations of the drill stem test and the subsequent flow tests of longer duration is notable. DST and flow test data would yield the same value of flow capacity if the DST flow rate were 0.52 MMCF/D. As discussed in Section 4, this would imply recovery of gas and oil. It is possible that an area around the well might have a higher permeability. Alternatively, a gas/liquid interface in the vicinity of the well and two-phase flow of oil and gas within the reservoir yield anomalous well test data. This seems a distinct possibility, and the well test interpretations are therefore considered tentative.

7. POSSIBLE STAIRWAY OIL RESOURCE

As discussed in previous sections, there is evidence of a gas/oil contact in the vicinity of East Mereenie 10.

The radius of investigation in DST #1 was 80 m, so the gas/oil contact would probably be within 50 m of the well. The implied contact level of 715 ± 3 m (2345 ± 10 ft) subsea differs from the gas/oil contact in the Pacoota P1 reservoir (649 m or 2130 ft subsea) indicating that the presumed Stairway oil reservoir is isolated. A different oil/water contact must also be present.

Figure 1 shows the possible extent of the oil pool based on an arbitrary Stairway oil/water contact at 852 m (2795 ft) subsea. The nature of western closure is unknown, but an oil accumulation covering 4.5 sq km is possible.

On this basis, and taking pay parameter in East Mereenie 10 as being representative of this area (and $B=1.4$), a possible oil resource of 4.3 million STB in place is suggested.

If the oil/water contact is lower, a significantly larger resource is possible.

EAST MEREEENIE 10 (LOWER STAIRWAY) - LOG INTERPRETATION

Number of data points	116
Borehole diameter (cm)	20.32

FORMATION FLUID PROPERTIES

Formation water resistivity (ohm-metre) .050

MUD FILTRATE PROPERTIES

Resistivity (ohm-metre)	0.000
Density (g/cc)	1.007

MATRIX PROPERTIES

Gamma ray minimum (API units)	28.0
Density (g/cc)	2.650

SHALE/CLAY PROPERTIES

Gamma ray maximum (API units)	240.0
Resistivity (ohm-metre)	70.00
Density (g/cc)	2.650

CUT-OFF LIMITS

Porosity minimum (%)	4.0
Water saturation maximum (%)	55.0
Shale volume maximum (%)	45.0

PAY DATA FOR INTERVAL 1402.1 TO 1437.1 METRES

Gross interval (metres)	35.1
Number of pay sands	5
Net pay (metres)	4.6
Average porosity (net, %)	5.6
Average water saturation (net, %)	18.1

PAY DATA FOR INTERVAL 1411.0 TO 1437.1 METRES

Gross interval (metres)	26.1
Number of pay sands	4
Net pay (metres)	4.0
Average porosity (net, %)	5.6
Average water saturation (net, %)	15.8

NOTES

Porosity was estimated from the density log
without correction for hydrocarbon effects

Water saturation was estimated from the dual laterolog without Rxo

Clay content was estimated from gamma-ray data

Data file used: L3EM10

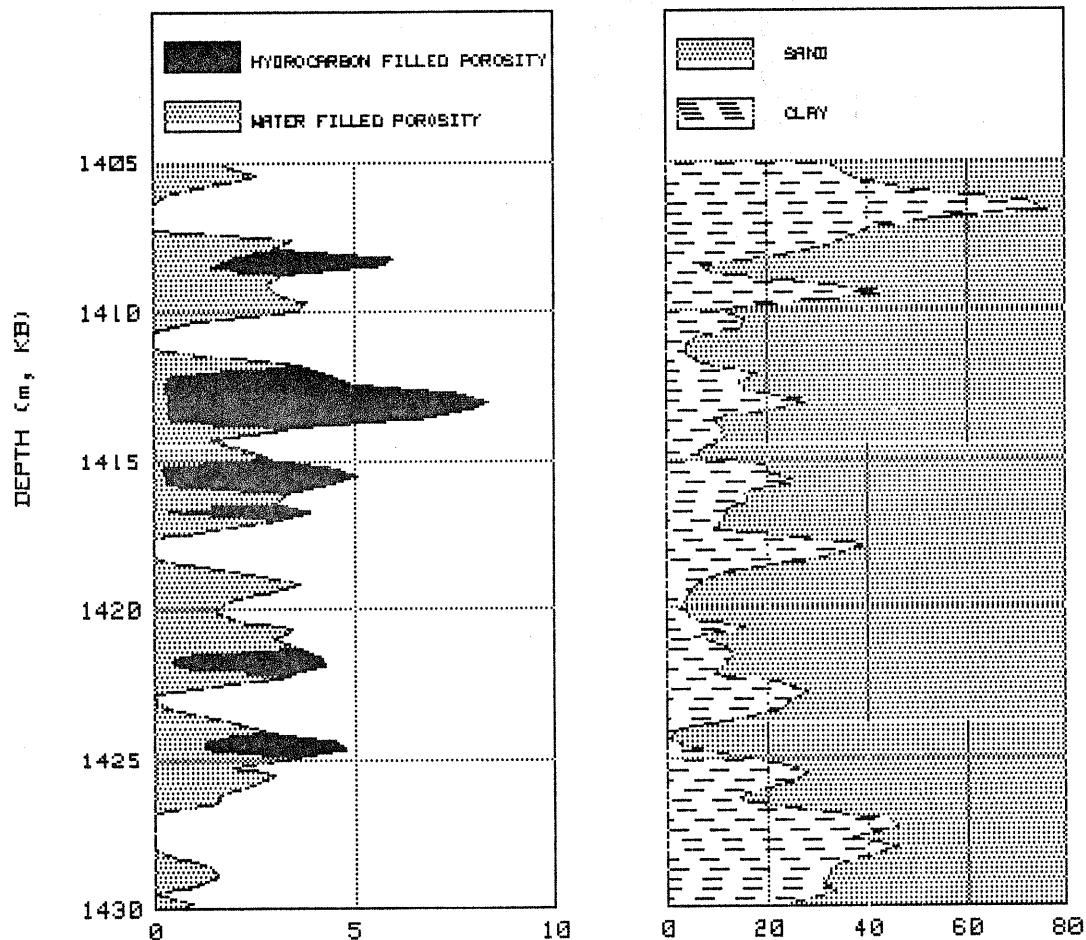

EAST MEREEENIE 10 (LOWER STAIRWAY) - LOG INTERPRETATION

SENSITIVITY ANALYSIS FOR INTERVAL 1402.1 TO 1437.1 METRES

POROSITY LIMIT (%)	NET PAY (m)	NUMBER OF SANDS	AVERAGE POROSITY (%)	AVERAGE WATER SATURATION (%)	HYDROCARBON CAPACITY (m)

EAST MEREEENIE 10 - AUGUST '84 TEST - SECOND BUILDUP

LOG-LOG INTERPRETATION

FORMATION TEMPERATURE: 59.6 °C
FORMATION VOLUME FACTOR @ 2115.5 psia: 1.107 RB/MSCF
MATCH POINT BUILDUP: 132.5 psi
MATCH POINT TIME .200 hours
APPARENT STORAGE COEFFICIENT: .056 RB/psi
ESTIMATED END OF STORAGE EFFECTS: 7.9 hours
POINTS REGRESSED: 7 TO 15
GRADIENT: 1.000

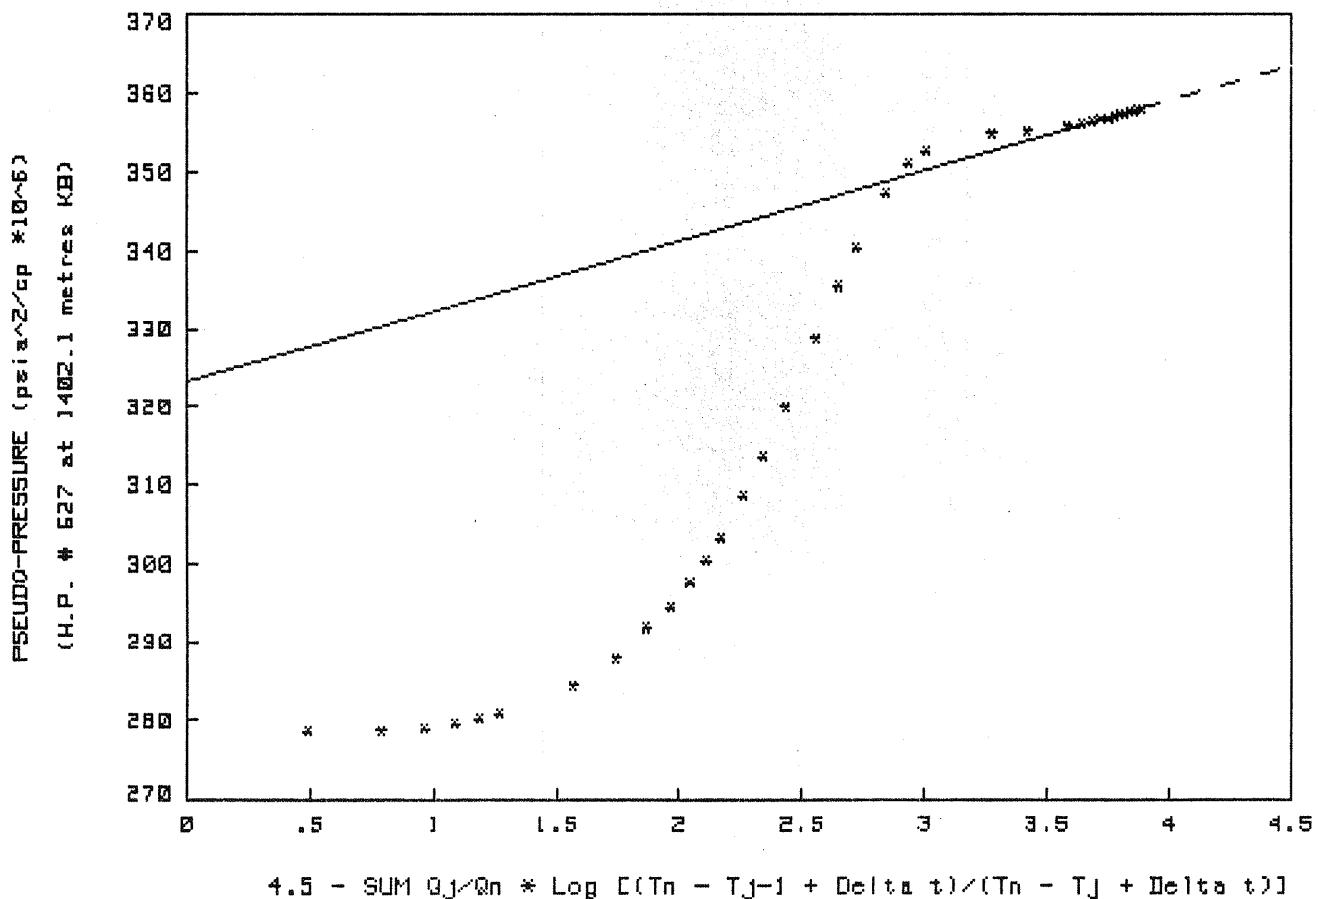

DATA FILES USED: B3EM10, GPVEMS

EAST MEREEENIE 10 - AUGUST '84 TEST - SECOND BUILDUP

FORMATION TEMPERATURE: 59.6 °C
FORMATION VOLUME FACTOR @ 2115.5 psia: 1.107 RB/MSCF
GAS VISCOSITY @ 2115.5 psia: .0189 cp
NET PAY THICKNESS: 4.6 metres (15.1 feet)
POROSITY: 5.6 %
GAS COMPRESSIBILITY @ 2115.5 psia: .0004967 /psi
FORMATION WATER COMPRESSIBILITY: .0000030 /psi
ROCK COMPRESSIBILITY: .0000050 /psi
WATER SATURATION: 18.1 %
TOTAL COMPRESSIBILITY: .0004123 /psi
WELLBORE RADIUS: 20.3 cm
FLOW CAPACITY: 48.3 md-ft
PSEUDO-PRESSURE Mp 1hr: 350.2 *10^6 psia^2/cp
PSEUDO-PRESSURE, INFINITE SHUT IN: 363.5 *10^6 psia^2/cp
PRESSURE AT INFINITE SHUT IN TIME: 2115.5 psia at 1402.1 m KB
AVERAGE PERMEABILITY: 3.2 md
SKIN FACTOR (TOTAL): 4.63 psi
DELTA P SKIN: 128 psi
RADIUS OF INVESTIGATION: 288 metres
POINTS REGRESSED: 29 TO 37
GRADIENT: 8.93 *10^6 psi^2/cp/cycle
COEFFICIENT OF DETERMINATION: .984

DATA FILES USED: B3EM10, GPVEMS
