EXPLORATION LICENCE No.6808 "LORELLA"

NORTHERN TERRITORY

FOURTH ANNUAL REPORT : YEAR ENDED 2nd NOVEMBER, 1994

1. INTRODUCTION AND SUMMARY

Exploration Licence No. 6808 "Lorella" is located approximately 960km by road southeast of Darwin, in the McArthur Basin. The licence covers approximately 104km². "Lorella" was granted for six years on November 2nd 1990.

The tenement covers areas of the Lower Tawallah and McArthur Groups which are postulated to be separated by the northerly extension of the Emu Fault, the "Pine Fault", which passes through the licence area. The area is considered prospective for base metals based on the similarity of structure and stratigraphy to that found at the HYC deposit.

The area has been explored in the past for base metals, phosphate, uranium and manganese with little result.

During 1994 a diamond core hole was drilled to test for potential extensions of copper mineralisation encountered in LD22, drilled the previous year. Diamond drillhole LD25 was completed at a depth of 353.6m and intersected ferruginous dolomitic siltstone containing visible native copper and galena between 297m and 306m. This zone yielded 3992ppm Cu and 2098ppm Pb. Downhole E.M. surveys conducted in drill holes LD22 and LD25 reported no significant conductors.

A small soil sampling survey was undertaken with no significant results reported.

Moderately significant Cu, Pb anomalism in ferruginous siltstones intersected in LD25 correlates well with that noted in LD22 and indicates mineralisation is continuous and stratabound.

2. LOCATION AND ACCESS

The Licence area lies on the Tawallah Range (6066) (1:100 000 scale) topographic map, approximately 100km NW from Borroloola or by road, 960km SE of Darwin, Northern Territory. The EL is bounded by latitude 15°30'S and 15°45'S and longitudes 135°53'E and 136°00'E (Fig. 1).

Access to EL6808 is by the Stuart Highway from Darwin to Daly Waters, the Carpentaria Highway to Borroloola, and along the Bing Bong road for approximately 72.5km to the turn-off to the Licence area.

Within the area there are numerous sand tracks which allow four-wheel drive vehicle access into most parts, although cross-country traverses are difficult due to the low and thick nature of the scrub. The terrain is mostly sandy with occasional black soil and Paper Bark swamps. Topographically the majority of the EL is flat lying.

3. TENURE

Exploration Licence No.6808 was applied for on 6th October 1989 and granted to Mount Isa Mines Limited on 2nd November 1990 for a term of six years. The area covered is 32 one-minute graticular blocks, which equals 104km². The NTDME expenditure commitment for the fourth year was \$100,000. There are no unusual conditions or requirements attached to the Licence.

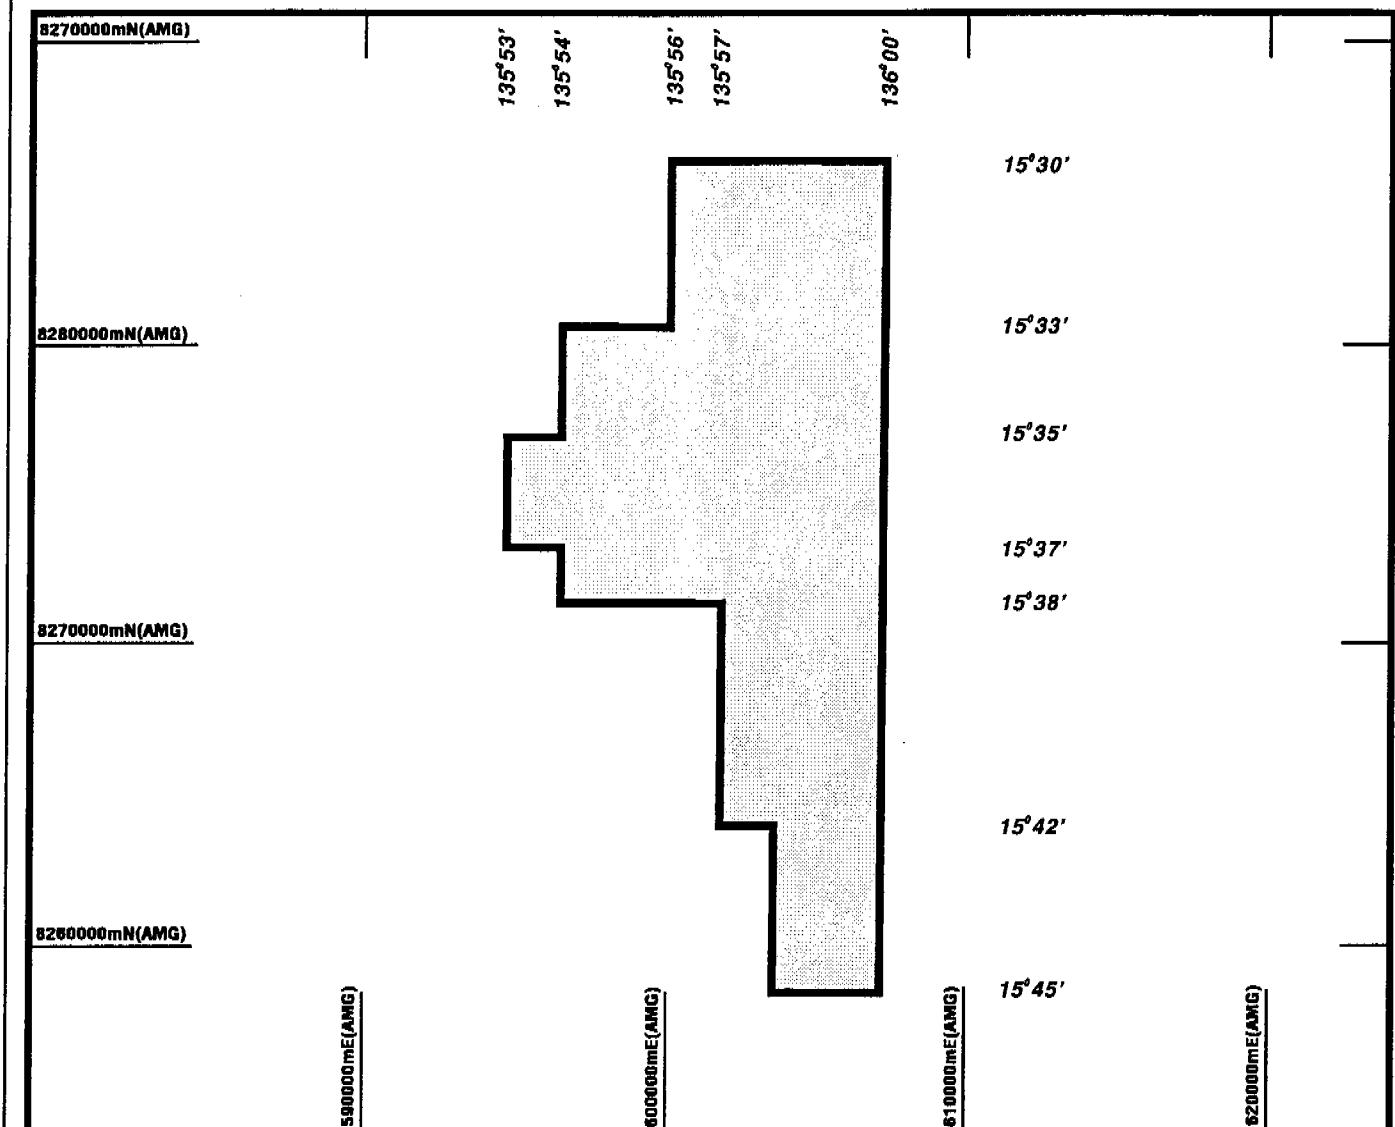

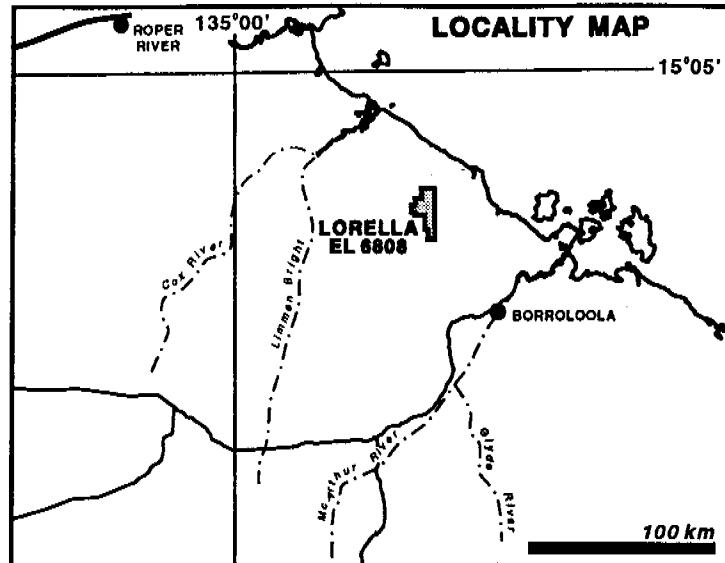

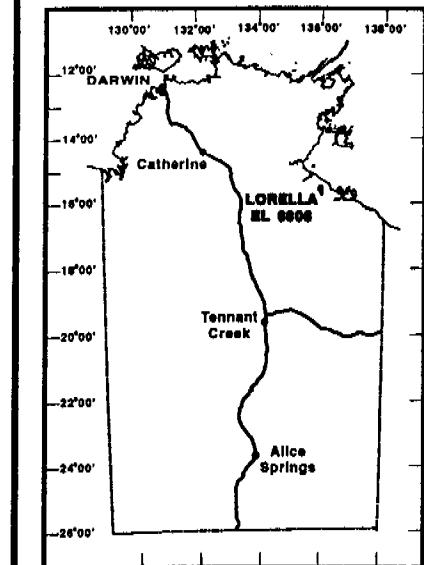

4. REGIONAL GEOLOGY

EL6808 "Lorella" is located within Carpentarian rocks of Lower-Middle Proterozoic age and lies on the Mt Young 1:250 000 Geological sheet area (SD53-15). The sequence of interest is the McArthur Group. Many base metal deposits within the North Australian Craton are hosted by this Group or its equivalents. This coupled with the projected extension to the Emu Fault through the middle of the Licence makes EL6808 prospective.

The McArthur Basin contains a thick platform-cover sequence overlying the eastern edge of the Northern Australian Craton which consists of Lower Proterozoic basement rocks (Jackson et al 1987) and has a stratigraphic succession similar to the Lawn Hill Platform and Mount Isa Orogen. The basin contains four rock groups: Roper (youngest), Nathan, McArthur and Tawallah (oldest). Only the McArthur and Tawallah Groups will be briefly discussed as they bear direct significance to the Exploration Licence reported herein.

4.1 Tawallah Group

The Tawallah Group is the oldest group in the McArthur Basin consisting mainly of thick sequence of ridge-forming sandstones alternating with units of recessive volcanics and fine grained clastics (Pietsch et al, 1991). It has an unconformable contact with the Scrutton Volcanics and has a maximum thickness from 4500 - 5200m.

M.I.M. EXPLORATION PTY. LTD. NORTHERN TERRITORY

1:250 000: Mt Young SD 53-15	Drawn: H.M.R.	Date: 22nd Nov. 1994
1:100 000: Tawallah Range 6066	Drawing No.	Figure No.: 1

4.2 McArthur Group

The McArthur Group overlies unconformably the Tawallah Group and comprises a sequence of interbedded carbonates and lutites with subordinate sandstones up to approximately 4200m thick (Jackson et al, 1987). The group is sub-divided into the Umbolooga Sub-group (older) and Batten Sub-group (younger).

4.3 Structure

The McArthur Basin is dominated structurally by the Batten Fault Zone, a north-trending zone 50-70km wide, flanked by the Wearyan Shelf to the east and the Bauhinia shelf to the west. This zone is thought to represent the site of a former syndepositional graben or half graben. Deformation of the Basin has mainly been in response to block-faulting along the Batten and Wapunga Fault zones causing the reversal of the graben structure into a horst or anticlinorium. This has lead to the exposure of the Scrutton Volcanics in the middle of the Batten Fault Zone (Jackson et al, 1987).

Broad folds and warping can be attributed to the faulting as well as drag folds, steep tilting, shearing, brecciation, veining and solution alteration effects. The faults have considerable strike-slip displacement as well as strike-slip with tension gashes in the Emu Fault Zone indicating right-lateral displacement of unknown magnitude (Jackson et al, 1987).

5. PREVIOUS EXPLORATION

In the late 1960's, Mount Isa Mines Limited, Geopeko and Australian Geophysical Pty Ltd held various portions of EL6808 "Lorella" (Table 1). Base metals were their primary target with phosphate and uranium being of secondary concern. All three companies considered the base metal potential of the "Lorella" area as unprospective and so no work was conducted.

In 1973 CRA Exploration covered the present tenement area under EL's 880 and 881. Low level aeromagnetics were flown and gravity surveys to geological mapping in an attempt to identify the Middle Proterozoic Barney Creek Formation. The exploration licences were surrendered in 1974 due to disappointing results.

The northern portion of EL6808 was held by Dampier Mining Co. in 1976. EL 1301 was the subject of intense manganese exploration. Only minor work was conducted over "Lorella". No economic manganese deposit was found and EL 1301 was surrendered in 1982. Similarly in 1976, EL's 1424 and 1425 were explored for manganese by Australia and New Zealand Exploration. A number of shallow auger holes were drilled in the present tenement area and although ferruginous manganiferous siltstone and laminated silty argillite with abundant manganese were intersected, an economic deposit was considered unlikely. The Licences were surrendered in 1977.

In 1976 the majority of EL6808 "Lorella" was held under EL's 1728 and 2072 by A.O. (Australia), in joint venture with Electrolytic Zinc Co., Pennaroya and Preussag Australia. In 1979 Shell Australia entered the joint venture and became the operators. Based on gravity anomalies a total of six diamond drill holes (BB 1-6) and 495 RAB drill holes were sunk on

EL1728. Similarly five diamond drill holes (WM1, 4-7) and sixteen percussion (WMP1A, 1-15) holes were drilled on EL2071. All drill holes were vertical. Barney Creek Formation was interpreted to have been intersected in many of the drill holes. Only low Cu-Pb-Zn values were returned. Shell sub-divided the Reward Dolomite into the upper mineralised Boko Beds Member and the lower mineralised Reward Dolomite. Based on drilling results Shell concluded that the gravity highs (+4 to +5 mgals) were associated with the Mara Dolomite and that gravity lows seemed to correlate with leached outcrops of Barney Creek Formation. Shell further concluded that the Barney Creek Formation found in this region was geochemically inactive and so development of an economic base metal deposit was not likely. Both Exploration Licences were surrendered in 1983. In 1984 BHP re-sampled some of the diamond drill core and tested for Cu-Pb-Zn. Results were discouraging with copper and lead values low and zinc peaking at 1400 ppm and averaging 378 ppm from 131 x 3m long core samples.

In 1982 CRA Exploration held the western portion of the present tenement area under EL4083. Selective gravel stream sediment samples were taken in the search for diamonds. Airborne magnetics and radiometric were flown resulting in twenty-seven aeromagnetic anomalies being defined. Seventeen of these lie in "Lorella". Scout auger drilling found the source of the anomalies to be sub-volcanic or volcanic rocks, laterite or ferruginous shales. No kimberlitic indicators were found so the Licence was surrendered in 1985.

BHP held five tenement areas, EL's 3578, 4240, 4277, 4678 and 4745, which covered the top and eastern sections of EL6808 "Lorella". A HYC equivalent base metal deposit was their target. Extensive airborne geophysics (aeromagnetics and radiometric) were flown to define ground targets. EM-37 soundings and limited gravity surveys over these targets were completed. Five vertical diamond drill holes (McA 17-21, totalling 1817.8m) were sunk over conductors defined by EM-37 soundings. Only two of the conductors (holes McA 19 and 20) were shown to be caused by the pyritic dolosiltstones, interpreted as Barney Creek Formation. Assay results were disappointing and correlation between the holes was poor. No further work was considered warranted so all Exploration Licences were surrendered by late 1986.

6. WORK BY M.I.M. EXPLORATION PTY. LTD.

6.1 Work done by MIM Exploration in 1991 - 1992

In 1991 MIM Exploration carried out two airborne QUESTEM surveys and one ground EM-37 sounding survey to regionally examine "Lorella" and better define a conductive zone defined by BHP in the mid-1980's. Successful completion resulted in three target areas being outlined. Seven diamond drill holes (LD1-7) were drilled to test the conductors. All showed that the conductors were caused by massive pyrite interbedded with black-dark grey pyritic, sometimes carbonaceous, dolosiltstone possibly of the Lynott Formation. Fourteen petrological samples were examined for general rock identification and possible insight to the origin of the pyrite. Minor rock chip sampling and geological mapping was also carried out.

Pisolite sampling of the surface ferruginous material was conducted with limited success.

During 1992, MIM Exploration carried out one in-fill airborne GEOTEM survey and one ground PROTEM sounding survey and two gravity (detailed and regional) surveys to better clarify airborne QUESTEM anomalies defined in the 1991 field season. This resulted in fifteen target areas being outlined. Eight diamond and six RC percussion drill holes were drilled for a combined total of 2337.40m to test the conductivity anomalies. The majority of these conductors seem to have been the result of near-surface ferruginous clays and laterite and minor ground water component. Holes LD10-11 and LP14-15 did intersect minor disseminated pyrite in dolosiltstone, most probably of the Lynott Formation, which may have produced a conducting response. Assays for Cu, Pb, Zn, Fe and Mn were routinely done.

Follow-up pisolite sampling over seventeen statistically anomalous areas generated by the work done in 1991 downgraded all sites. No definite anomalies were interpreted. It would appear that the anomalous values generated in both years work are the result of accumulation and concentration due to transportation by water and do not seem to indicate sub-surface leaching.

Results from lead isotope work conducted by the CSIRO on diamond core suggests that the majority of the samples show *in situ* radioactive decay of U and Pb. Also the isochron age of all samples seems to indicate a much younger source than the source for the HYC deposit. An epigenetic origin of the lead mineralisation at "Lorella" has been inferred from the work.

The geological mapping and photo lineament study were completed. The tenement has numerous, previously unmapped, outcrops of the McArthur Group (including: Yalco Formation and Hot Springs and Caranbirini Members of the Lynott Formation) and Tawallah Group (Warramana Sandstone, Wollogorang Formation and Wununmantyla Sandstone).

Stockdale Prospecting Ltd entered into an agreement with MIM Exploration Pty Ltd on the 14th July 1992 to enable them to explore for diamonds on EL6808 "Lorella". Three aeromagnetic anomalies (two in the central and one to the northeast boundary of the area) were singled out for ground follow-up.

6.2 Work done by M.I.M Exploration in 1992 - 1993

In 1992 - 1993, guided by interpretation of gravity and aeromagnetic data, M.I.M. Exploration Pty Ltd carried out a detailed SIROTEM sounding survey to provide greater definition of conductors located in previous E.M. surveys (SIROTEM; BHP 1982-4 and PROTEM; M.I.M in 1994).

Three diamond drillholes were drilled, for a combined total of 753m, to test targets generated by the SIROTEM survey. In drillhole LD22 the conductive target was interpreted to be the intensely clay altered contact between Hot Springs and Caranbirini Members of the Lynott Formation. Drillholes LD23 and LD24 intersected resistive stratigraphy considered to be unprospective Tawallah Group.

Laterite exposures were mapped to ascertain whether they were surface expressions of lineaments. Comparison of the outcrop map and the gravity/aeromagnetic lineament map

did show some correlation between position of exposures and lineaments.

Geological mapping pinpointed outcrops previously assigned to Warramana Sandstone, but now considered to be Cretaceous sandstones.

6.3 Drilling 1994

Diamond hole LD22 drilled in 1993 encountered anomalous copper in breccia near the base of the hole. A diamond core hole 200m west of LD22 was proposed to test for potential extensions of copper mineralisation.

A single angled core hole LD25 was drilled to a total depth of 353.6m, comprising 138m of R.C. percussion and 215.6m of H.Q. core.

The R.C. percussion precollar was sampled from 6 to 138m and assayed on 2m composites, with a total of 66 samples submitted and assayed for Cu, Pb, Zn, Fe and Mn.

Core, selected by presence of visible mineralisation was sampled in continuous 1m splits, where core loss was minimal, or between core run markers in zones of severe core loss. A total of 35 half core samples were initially assayed for Cu, Pb, Zn, Fe and Mn by AAS with 16 pulp samples reassayed for Cu, Pb, Zn, Fe and Mn and, in addition, assayed for Ag, As, Co, Mo, Ni, V, Bi, Cd, Sb, Se, Sr, Th, Te, Ba, Au, Sn, Ta and W.

Drill logs and assays for LD25 appear in Appendix 1.

Sample Ledgers with details of sample numbers, intervals and core recoveries are found in Appendix 2.

6.3.1 LD25 Downhole Geology

LD25 was collared in unconsolidated sand resting on weathered Cretaceous sandstone and mudstone which continued to a depth of 29m. 6m of clay was then encountered from 29 to 35m before passing into mainly leached silicified mudstone and minor arenite from 35 to 146.5m. From 146.5 to 229.8m, tectonically disrupted sedimentary breccia dominates, alternating with minor thin dolomitic arenite and siltstone. A nodular chert zone then occurs from 229.8 to 269.7m.

Below the nodular unit a zone of ferruginous dolomitic siltstone and sedimentary breccia from 269.7m to 295m is followed from 295 to 306.3m, by a strongly ferruginous clayey siltstone with traces of visible native copper. Thin crusts of galena were also observed. A breccia zone was then intersected from 306.3 to 318m comprising dolostone clasts, up to 30cm across in a green clay matrix.

From 318 to 353.6m (E.O.H.) solution-altered, fractured or brecciated dolosiltstone and dolarenite occur.

Pervasive solution-alteration and leaching has left little original fresh rock.

6.3.2 LD25 Downhole Geochemistry

101 samples were submitted for assay. Downhole assay results are summarized below:

	PEAK (ppm)	AVERAGE (ppm)	RANGE (ppm)
Cu	7890	423	3 - 7890
Pb	7420	271	4 - 7420
Zn	220	37	2 - 220
Fe	28.3%	3.45	0.4% - 28.3%
Mn	42700	3681	21 - 42700

A significant intersection occurs at 297m with: 9m at 0.40% Cu and 0.21% Pb from 297m.

6.3.3 DHEM Survey LD22 and LD25

In August 1994 DHEM surveys were conducted down diamond drill holes LD22 and LD25. The aim of the surveys was to detect possible accumulations of massive sulphide, in particular chalcopyrite, within a radius of 80 - 100m away from the hole.

The surveys were conducted by contractor Solo Geophysics, employing the following specifications:

Receiver:	Siretom MK III
Transmitter:	SA-TX
Time Series:	Early Times
Sampling Delay:	0 microseconds
Gain:	1
Reading Increment:	10m

The Loop locations relative to the hole collars are presented in Figure 2. One loop was used for each hole.

Results

The DHEM data is presented as profile plots in figures 3 and 4.

No significant anomalies have been detected in both surveys. The steady migration from positive to negative in the early time channels is interpreted to be the response of the country rock and/or conductive overburden.

Siro-ex : TEM Response Profile

Fixed Loop Tx, Downhole Dipole Rx, A Component

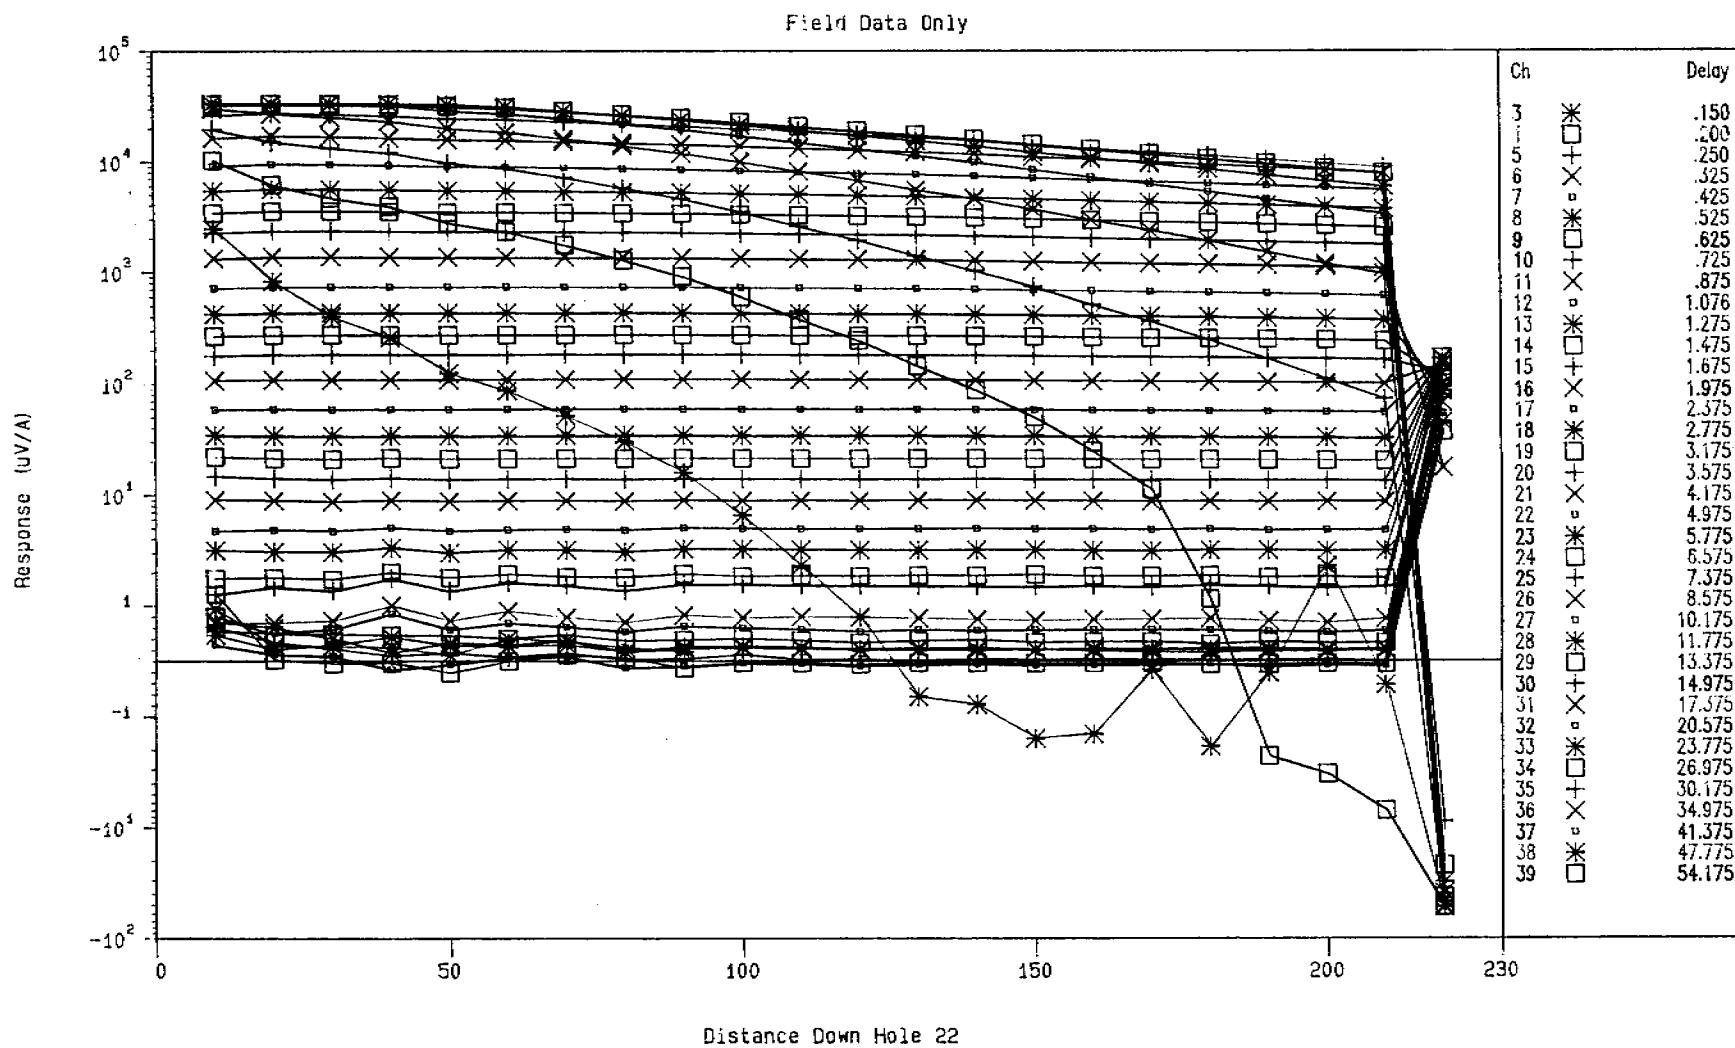

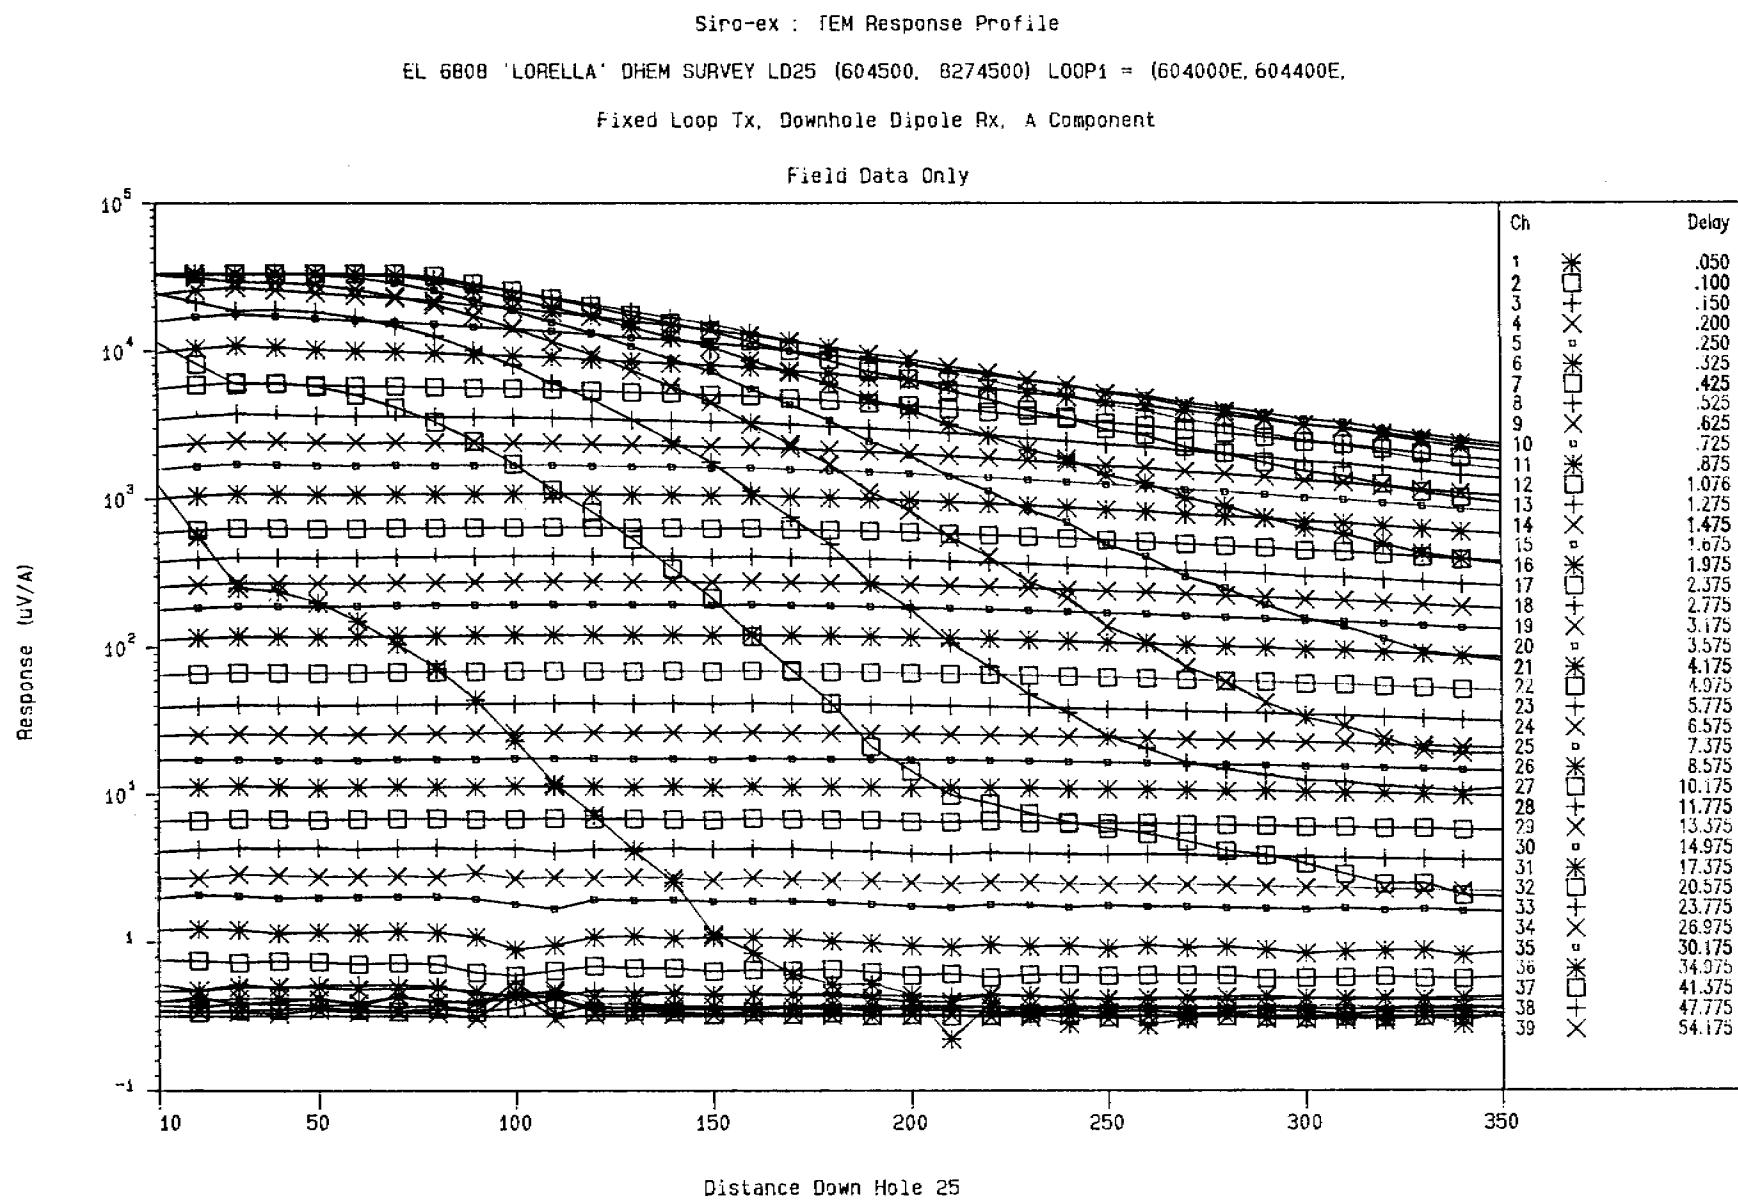

Fig 3

FIG 4

6.4 Soil Sampling 1994

Fifty-one soil samples were collected over a 2.5km east-west traverse, at 50m spacing, on gridline 82764OON from 6035OOE to 605985E.

All samples were analysed for a suite of elements using partial extraction techniques.

Results were subdued and probably reflect the general lack of geochemical response from surface material at Lorella.

Results are tabulated in Appendix 3 and sample locations are presented on Drawing 41706.

7. CONCLUSIONS

Moderately significant Cu, Pb and associated Fe, Mn anomalism in ferruginous siltstone intersected in LD25 correlates well with that noted in LD22, drilled in the previous year, and indicates mineralisation in continuous and stratabound.

Trevor Pilcher
Project Geologist - Northern Territory

FROM	TO	REC.	GEOLOGY	CODE
138	146.5		White to pale grey, lesser pale green and pink tints, oxidised yellow brown cherty or silicified dolosiltstone, intense tectonic brecciation, network microfractures, clay alteration, hematitic veining. CBA's 138-143 30-45°, 143-146.5 0°	
146.5	150.7		Tectonic Breccia, yellow brown clay pug with large fragments of pale grey cherty dolosiltstone tailing subparallel to core from 146.5-147.3 and 30-50° CAA. Mn + Fe veining common, a leached fine to medium grained arenite from 147 to 149m.	
150.7	165.		Brecciated and intensely disrupted pink-green, red brown, yellow and pale grey, thin bedded (mainly) leached dolosiltstone with minor arenite ferruginous and partly silicified.	
150.7	151.2		red brown soft siltstone.	
151.2	for 80cm.		white to grey dolosiltstone, cherty and clayey in part.	
152	- 165.		CBA's variable, from 45° to 0°, tectonic breccia comprising milled fragments in pale green clay matrix and both clast and matrix supported. at 153.65 good evidence of faulting cutting bedding, as shown in diagrams.	
a) 153.65 ferruginous —				
Siltstone CBA = 50°			tectonic breccia (pug)	
FBT = 30°			faultaxist	
163.6. fragments of brown chert/siderite.				
165	187.2		pale grey, pale-apple green, pale pink, leached chert and clay siltstone. altered dolosiltstone, siltstone and thin silty arenite, tectonically brecciated.	
165 - 167.6 tectonic breccia				
165 - 165.4 fractured brecciated cherty dolosiltstone, strong clay solution alteration, weathered out stylolite at 165.15, chert/siderite lenses and vein-fills.
